We welcome your most cordial agreement with the broad principle involved in this matter, and the adoption of the recommendation would mean that the Board of Trade Committee referred to would have rendered some signal service to humanity.—I am, Sir, yours faithfully,

T. W. MOORE,
Secretary, The Imperial Merchant Service Guild.

Liverpool, Oct. 23rd, 1911.

THE TECHNIQUE OF SALVARSAN INJECTION.

To the Editor of THE LANCET.

SIR,—I was interested in your annotation in THE LANCET of Oct. 14th dealing with the intravenous injection of salvarsan. It has always occurred to me that there must be more risk in the intravenous method, and I have carefully avoided it. My experience of the use of salvarsan now extends to 14 cases, and I have made all the injections deep into the buttock just above and behind the great trochanter in order to avoid the sciatic nerve. Twelve of my cases

were of the resistant type of tertiary syphilis, with marked gummatous, tubercular, and ulcerative lesions. In all these cases the lesions healed or disappeared in the most remarkable manner and within three to six weeks. In no case so far have I given any subsequent mercurial or iodide treatment. A full dose of 0·6 gramme was administered. At first I confined the patients to bed for six days after the injection, but I do not now recognise the necessity, when all has gone well, for confinement to bed for more than two days. There were two instances of the injection having been given in the out-patient room of the hospital, but I asked the medical attendant to kindly see that these men rested quietly at home for two or three days. I also gave orders that they should be taken home very quietly. Both did well and with no untoward symptoms whatever.

I have always used a neutral solution, well stirring it as I draw it into the syringe. To avoid blocking, a wide-bored needle is a necessity. In the large majority of cases there were no complaints of any after local pain, and the complaints made by the majority were comparatively trifling. The skin surface was disinfected with iodine, and the syringe and needles taken straight from the steriliser. One of the 14 cases was that of a secondary syphilide with the primary chancre still in evidence, and the other unaccounted for was a doubtful case of syphilis, a lymphangitis of the lower lip in a young man, which had been treated otherwise unsuccessfully at the London Hospital and by myself at the Royal Berkshire Hospital. Barely two years have elapsed since I injected my first case and some were injected only a few months or a few weeks ago, therefore it is too early to speak of the permanence of the cure; but it is at all events permanent within the above range-limit of time, and all patients so far have been kept under due observation. The solution, or rather emulsion, was injected within half an hour or within a few minutes of its final mixing and testing.

I am, Sir, yours faithfully,

Reading, Oct. 17th, 1911. W. T. FREEMAN.

PRURITUS ANI.

To the Editor of THE LANCET.

SIR,—Apropos of your annotation on Dr. Dwight Murray's paper, will you permit me to record a few observations of my own? I have had occasion to treat or advise many patients suffering from this complaint. X rays and high-frequency currents have generally been followed by temporary cessation of the symptoms, but I have always felt that this may have been due to more methodical cleanliness on the part of the patient during the course of treatment. I have succeeded in cultivating staphylococci, streptococci, and bacilli coli from the anal folds of pruritic patients, but as these bacteria can often be grown from the ani of unaffected persons it seemed hardly logical to adopt vaccine therapy, especially as the following simple treatment is almost always eventually effectual.

Thorough washing of the parts at the earliest opportunity after defæcation. Should the patient's occupation prevent this being done at the time it must be done when dressing for dinner or before going to bed. The parts are then anointed with some simple sterile lubricant such as almond oil. If there is itching, scratching to a moderate extent may be permitted under sterile conditions—i.e., the hands and nails must be absolutely clean. In the early stage of treatment itching may recur during the night, and this may be instantly relieved by the application of a very minute quantity of salicylate of soda.

The anal folds smeared with an imperceptible layer of fæcal matter form an ideal medium for the growth of bacilli of the coli group, all of which are motile. The movement of the bacteria in the neighbourhood of the nerve-endings may well cause itching. In young, healthy people pruritus ani is rare, and possibly the secretions of the sebaceous follicles may here have an adverse influence on the bacilli that find their way through the sphincters. In old people these secretions may become scanty or inert, and this may possibly be an explanation of the frequency of the complaint in such people. Any way, I find that, although the complaint is completely held in check by the treatment I have indicated, this has to be continuous and be carried out as a matter of routine through life.

It seems highly probable that the moderate scratching, with precautions to avoid abrasion of the skin and inoculation with foreign micro-organisms, may not only remove any remaining colonies of bacteria, but may induce slight leucocytosis and the destruction of those bacteria which Dr. Murray thinks penetrate the skin. Scratching is Nature's cure, and there are many parallel instances where natural inclination intelligently guided is found to be the best remedy. The application of the common antiseptics often aggravates the complaint by causing local irritation, and possibly by interfering with the natural physiological processes that make for relief.

I am, Sir, yours faithfully,

Oban, Oct. 21st, 1911. W. D. ANDERSON.

THE THIRD TRIENNIAL CONGRESS OF THE INTERNATIONAL SURGICAL SOCIETY AT BRUSSELS.

(FROM A SPECIAL CORRESPONDENT.)

IN an annotation in THE LANCET of Oct. 21st brief reference was made to the success of this Congress.

Subjects under Discussion.

The subjects chosen for discussion were: (1) Pancreatitis; (2) The Surgery of the Lungs and Pleuræ; and (3) Colitis. These were discussed under the following headings: 1. The Diagnosis of Pancreatitis; Reporter, Dr. Michel (Nancy). 2. The Treatment of Acute Pancreatitis; Reporters, Professor Körte (Berlin) and Dr. Giordano (Venice). 3. The Prevention of Operative Pneumothorax; Reporter, Professor Garrè (Bonn). 4. The Operative Treatment of Pulmonary Emphysema; Reporter, Professor Garrè (Bonn). 5. The Treatment of Purulent Pleurisy; Reporter, Professor Gaudier (Lille). 6. The Treatment of Pleural Sinuses; Reporter, Dr. Girard (Geneva). 7. Wounds of the Pleuræ and Lungs; Reporter, Dr. Lenormant (Paris). 8. Parasites and Tumours of the Lungs and Pleuræ; Reporter, Professor Hugh Ferguson (Chicago). 9. The Surgical Treatment of Pulmonary Tuberculosis; Reporter, Professor Friedrich (Magdeburg). 10. Acute Colitis; Reporter, Professor Sonnenburg (Berlin). 11. The Treatment of Chronic Colitis; Reporters, Mr. D'Arcy Power (London) and Professor Segond (Paris). 12. Valvular Cæcostomy in the Treatment of Colitis; Reporter, Dr. Gibson (New York).

In the limited space available it is quite impossible to deal adequately with the very valuable reports on the different subjects, still less with the discussions which followed. Some few points may, however, be mentioned. Dr. Michel considers the Cammidge reaction of decided value in the diagnosis of pancreatic disease, notwithstanding the numerous adverse criticisms which have been directed against it.

Surgery of Lungs and Pleuræ.

With regard to the various forms of apparatus at present employed for the prevention of pneumothorax during the course of operations on the thorax Dr. Garrè thinks that none of them are quite satisfactory in spite of the great ingenuity which is displayed in their design and the marked improvement in technique which has attended their use. In cases of pulmonary emphysema Dr. Garrè recommends operation in the condition termed by Freund "the rigid, dilated thorax." The procedure he advocates is the resection of the second to the fifth (inclusive) costal cartilages on one side. By this method the respiratory capacity of the lungs may be doubled. His clinical observations over a period of three years have proved the value of this line of treatment. Unsatisfactory results are due principally to operation being undertaken at too late a stage or in unsuitable cases, as, for instance, when the immobility of the chest wall is due to causes other than calcification of the costal cartilages.

In dealing with wounds involving the pleura and lung Dr. Lenormant considers that treatment simply by occlusion of the external wound and keeping the patient absolutely at rest gives very good results in the great majority of cases, and should be the method of choice in the absence of pressing indications. Aspiration of a large hæmothorax causing urgent dyspnœa, pleurotomy in cases of suffocating pneumothorax, early pleurotomy in the presence of symptoms of pleural infection, will meet all indications in most cases. Only very rarely will it be necessary to

deal directly with a wounded lung. Direct surgical intervention in cases of pulmonary wound is a serious and difficult operation attended with a mortality of about 33 per cent. (statistics of 133 cases submitted to operation), and should only be undertaken in the event of severe primary or secondary hæmorrhage after treatment by absolute rest has proved unavailing. Dr. Lenormant insists on the need for free opening in the thoracic parietes and systematic exploration of the injured lung, as the lesions are often multiple, especially in gunshot wounds. Drainage of the pleura greatly increases the risks of infection (15 per cent. in undrained, 42 per cent. in drained cases), and should not, therefore, be employed unless when special indications such as imperfect hæmostasis or already existing infection are present.

In speaking of the surgical treatment of pulmonary tuberculosis, Professor Friedrich said that in cases of fibroid phthisis with cavities, especially in unilateral, chronic, or apyretic cases which are getting worse in spite of proper medical and climatic treatment, and in which the prospect of recovery is steadily becoming more doubtful, if the patient's general condition is sufficiently good and the age between 15 and 35 years, operative measures may be considered and even recommended. Slight or quiescent areas of tuberculosis in the opposite lung need not be considered as contra-indications. Notwithstanding the heavy mortality (8 in 27 cases), Professor Friedrich considers, due regard being given to the serious nature of the cases treated, that the results of operation are decidedly encouraging. It is, however, essential that the cases should be most carefully selected.

Sir William Macewen referred to three cases of pulmonary phthisis on which he had operated, one of which was particularly interesting because it had been found necessary to extirpate the whole of the left lung and the patient had recovered, and still 15 years after the operation, remained well and followed an occupation involving very hard work.

Colitis.

Mr. D'Arcy Power, speaking on the treatment of chronic colitis, said that when it is clearly recognised that a patient is suffering from ulcerative colitis and is not improving under ordinary treatment the sooner an appendicostomy is performed the better. But appendicostomy, though resulting in great improvement, Mr. Power has found to be insufficient to effect a complete cure, and he thinks that the best line of treatment lies in a combination of appendicostomy with vaccino-therapy. Mr. Power also showed a three-colour photograph of a fresh post-mortem specimen of ulcerative colitis, which very beautifully reproduced the original appearances.

The Exhibition of Fractures.

The great success which had attended the Cancer Exhibition at the second congress and the marked interest displayed in it had encouraged the committee to provide a corresponding attraction on the present occasion. In view of the world-wide revival of interest in their treatment no better subject than that of fractures could have been chosen. The choice was also singularly appropriate in view of the fact that the Presidential chair was filled by Professor Lucas-Championnière, whose name is so widely associated with and who has done so much to improve the treatment of fractures.

Amongst the most interesting exhibits were: (*a*) life-sized models showing the application of Bardenheuer's methods and radiographs illustrating the results obtained; (*b*) Lucas-Championnière's radiographs of articular fractures treated by massage and early movement; (*c*) Marbaix's radiographs of fractures of the neck of the humerus, the olecranon, and in the vicinity of the wrist, treated by immediate movement and massage without reduction and without retentive apparatus; and (*d*) Dollinger's plaster apparatus for the ambulatory treatment of fractures of the thigh and leg, and his plaster bandages for the treatment of fractures of the humerus and femur in new-born children. Probably, however, Lambotte's and Arbuthnot Lane's series of radiographs, showing the results obtained by the operative methods with which their names are associated, attracted the greatest attention.

Another interesting exhibit was Professor Kummell's series of radiographs illustrating the marked tendency of fractured bones in young individuals ultimately to recover their normal form, even when the original deformity had been very great and had not been corrected by treatment.

Hospitality at the Congress.

No account of the Congress at Brussels would be complete without mention of the magnificent hospitality offered to the visiting members by both the medical men and the leading citizens of the town. In many cases the delegates came with their wives, and these were invited also to the dinners and receptions and to a gala performance of *Orphée et Eurydice* at the Opera House, where Madame Croiza gave her services gratuitously. In addition, Brussels ladies lent their own cars and took the ladies of the party for two delightful drives. Madame Depage, Madame Lorthioir, Madame Verhoogen, and Madame Willems invited guests nightly to their beautiful houses. There were also three receptions, the first at Dr. Lorthioir's, where Dr. Lucas-Championnière, the President, received the delegates and their wives; the second at Baron and Baroness Lambert de Rothschild's, whose house is said to be the finest in Brussels; and the last at the beautiful town-hall. When it is considered that this is the third congress running which has been held in Brussels, the population of which is only 400,000, one feels all the more the generosity of the medical men and their wives and of many other citizens.

THE EFFECTS OF THE STRIKE ON THE LIVERPOOL SANITARY SERVICES AND THE DEATH-RATE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

Liverpool, October.

Measures for the Protection of Infant Life.

WHAT the population of Liverpool has suffered in consequence of the recent widespread strikes has not been fully explained or realised. Indeed, the after-consequences are still making themselves felt and the death-roll is not yet closed. The pity of it is that it seemed, on the contrary, as if the effort of years was about to receive a well-merited reward. When the number of deaths resulting from epidemic diarrhœa during the first weeks of this year's remarkable summer were compared with the figures of the exceptionally hot seasons of 1897 and 1904 it seemed as if Liverpool would escape the usual consequences of very high temperature. Though the heat this summer was greater than that of the two hottest years of recent times the number of deaths was at first less than on those two occasions. The fact is that the sanitary control of the city has been constantly extended and improved. Besides, special attention is bestowed on the prevalence of epidemic diarrhœa among children during the hot weather. A large staff of female inspectors is now employed to visit the homes of the poor and give the parents advice in regard to the proper feeding and care of infants. Instructive posters and leaflets are distributed freely. Moreover, an extra large staff of scavengers is engaged to wash out the courts, alleys, and smaller streets of the poorer quarters. This is not done now and then, but every day. The trough water-closets in some of the courts and the courts themselves are cleared out twice a day, and stable middens are so sprayed with lime as to prevent the breeding of flies. In 1897 and 1904 the measures taken were not so energetic and thorough. Though the meteorological conditions during those two years were the nearest approach to what we have just experienced, the weather was neither so hot nor so dry. Nevertheless, by the beginning of July the infant mortality commenced to rise by leaps and bounds. This year, on the contrary, there was only a comparatively small increase of cases up to August 7th. By that time, however, the great strike had thrown all the sanitary services out of gear. The loss of life that immediately followed will at least serve to show how very effective these services had been.

The Death-rate of the Children and the Strike.

On Sept. 21st last the health committee of the Liverpool Corporation requested the medical officer to prepare a report setting forth exactly what had occurred. This report has just been printed, and Dr. E. W. Hope, the medical officer of health, has kindly forwarded me an early copy.

The statistics therein set forth show that the population of Liverpool is estimated, in the Census of 1911, at 747,627, and the actual deaths from diarrhœa were 20, 23, 38, and 46 during the four weeks of July last. The lowest number of deaths from all causes during that month was 227 in the second week, and this is equal to an annual death-rate of 15 per 1000 of the population. The highest number of deaths was 272 in the fourth week, and this raised the death-rate to 18 per 1000 per annum. During the month of July the average temperature was 64·1° F., and the rainfall only amounted to 0·3 inch. The average July temperature for the previous five years is 58·9° F. and the rainfall 2·4 inches. Out of the population, then estimated at 734,673, the average for the last five years shows 4, 6, 9, and 11 deaths from diarrhœa during the four July weeks, and the general death-rate for each week was equal to 15 per 1000 per annum. For the four weeks in August during these five years (1906 to 1910) the average deaths from diarrhœa were 23, 34, 52, and 63; the general death-rate rose from 15 to 19 per 1000. The average temperature was 59·5° and the rainfall 2·4 inches. The last three weeks of August this year correspond with the strike weeks, when the trouble began on August 5th and reached its most disastrous development on August 17th. This year the average temperature was 68·8°, and though there had hardly been any rain the previous month only 2·7 inches of rain fell in August. This may account for the fact that before the strike commenced, and in spite of the energetic sanitary measures, there were 81 deaths from diarrhœa during the first week and the general death-rate rose to 20 per 1000 per annum. The interruption of the sanitary services and the general disturbance resulting from the strike may be considered as the principal cause of the further and great increase of mortality. For the second week of August we have a death-rate of 24 per 1000, including 132 deaths from diarrhœa. The maximum mortality was recorded during the third week of August, which was the worst week of the strike. There were 159 deaths from diarrhœa, and the general death-rate was equal to 27 per 1000. But no sooner was it possible to begin to restore the sanitary services than the public health began to improve. Thus during the fourth week of August there were 140 deaths from diarrhœa, and the general death-rate descended to 24 per 1000.

The General Death-rate and the Strike.

It will, however, be easily understood that it took some time for the full effects of the evil conditions created to manifest themselves. With infants and young children the increase of sickness was more rapid and the decrease more prompt. Thus the deaths from diarrhœa during last September, though not so numerous, remained very high. They amounted for the four weeks to 148, 130, 109, and 112, notwithstanding the fact that the temperature fell, the average being 58·500, and there was more rain—namely, 3·4 inches. But this is not all due to the strike, for in normal times there are more deaths in September. The average of the previous five years shows that the general death-rate varied from 19 to 20 per 1000, and the total deaths from diarrhœa for the four weeks were, on the average of the five years, 60, 58, 46, and 41. This is higher than the two previous months. Indeed, the four worst weeks of the year in normal times are the last two of August and the first two of September. It so happened that effects of the strike coincided with the end of August. The effect on the general death-rate also coincides with the strike. In the first week of August and before the strike could have any influence the death-rate was affected by the great heat and had risen to 20 per 1000. The second week, when the strike was in progress, it rose to 24 per 1000, and the third week, when the strike had wrought its worst, it was at 27 per 1000. After that there were fluctuations, for during the fourth week in August the death-rate fell to 24 per 1000, then it rose again to 26 per 1000 in the first week, and 27 in the second week of September. Subsequently it fell to 23, and rose again to 25 per 1000 in the third and fourth weeks of September.

These figures very clearly indicate that the exceptionally hot weather did aggravate the situation, and that the strike intensified the evil to an alarming and disastrous extent. For a period of about two weeks it is probable that a third of the deaths from diarrhœa were due to the strike, and for some weeks following a smaller proportion of deaths from this cause were also due to the after-effects of the unwholesome conditions prevailing during the strike. But to judge from the figures given above relating to the general death-rate there seems to have been a notable increase of mortality from other causes, and this prevailed among adults as well as among children. These fatal results were obviously caused by the extreme, almost tropical heat, and the accumulation of filth, together with the want of food, especially of milk. Some 300 butchers' shops had to close their doors because they could not obtain any meat; but the interruption of the milk-supply had a more direct immediate effect on infants. Even the hospitals suffered, in spite of the efforts of the strike committee to secure the safe delivery of what was needed for the care of the sick. The angry crowd could not always distinguish between provisions for the hospitals and the vans conducted by strike breakers. Then parents, even mothers, carried away by the excitement of the moment, were apt to neglect their children, leaving them to play about the accumulating filth of the courts and alleys. The work of sanitary inspection stopped and the lady inspectors, who do such good work in advising mothers, could not penetrate into the disturbed districts.

The Insanitary Conditions Caused by the Strike.

Probably the worst evil of all was the interruption of scavenging services. In the better parts of the town this did not so much matter. Here the inhabitants were able to take care of themselves. They understood the importance of cleanliness, and though their domestic refuse accumulated and could not be removed, they endeavoured to burn a large proportion of it themselves, to sprinkle disinfectants over the rest, and cover it up so that it should not become a breeding ground for flies. Thus, no very great nuisance arose in the better quarters of Liverpool. But in the poor districts a few hours' neglect suffices for dangerous conditions to come into existence. Though closets are provided, there is nevertheless a considerable amount of fæcal matter in the courts. Adults sometimes do not take the trouble to go to the closets, and children habitually do all they need in the open air. Thus, the garbage that accumulates in these localities is much more dangerous than it would be among a more civilised population. To keep down this nuisance a special staff of scavengers scour out these streets and courts every day with the fire-hose and sweep everything down into the sewer. Further, they visit the inside of the houses, and if they find a neglected, dirty closet, the inhabitant is called upon to clean it forthwith while the inspector stands by and sees that it is properly done. If there is any resistance a summons is taken out at once, and the responsible parties have to appear before the police court to answer a charge of creating a nuisance. But during the strike, and for five to six days, this service entirely stopped. Then great poverty prevailed. What little milk was procured was more readily contaminated when brought into such filthy surroundings. Had this continued, something far more dangerous than an increased mortality from diarrhœa among children might have ensued. Cholera, or even plague, might have found favouring conditions amid all this poverty and dirt.

The Strike and the Disposal of Refuse.

Nor was it easy to bring matters back to normal conditions when the strike was over. With the courteous assistance of the sanitary officers I was able to visit the great destructor in Charles-street. Here there is a wharf, and a certain sort of refuse is discharged into barges. It is then conveyed along the Leeds canal to be delivered at different points where it can be utilised for agriculture. No less than 600 tons of refuse are brought every day from the streets of Liverpool to this destructor. About a third, or 200 tons, are burnt forthwith. The rest is sorted and conveyed away by the barges. During the strike, instead of 600 tons, barely 100 tons were brought in the 24 hours. Thus refuse, garbage, and filth of all sorts were accumulating in the courts and streets of Liverpool at the rate of 500 tons a day.

The dealing with this refuse is so well managed that it brings in about £3000 annually. For instance, oyster shells are sorted out and ground up for chickens, and thus they return to our table in the form of egg shells. All tin, iron hoops, and fairly pliable metallic scraps are placed in a compressing machine. A sort of funnel 6 feet long is filled up with these scraps, and then the loose contents are pressed down into a compact mass 25 inches in diameter,

6 inches in depth, and weighing about a hundredweight. Thus rendered easy to handle and transport, it can be more readily conveyed to where it is utilised and consequently finds many purchasers. Some of the clinkers from the furnace are sent away for road making. Others are ground on the spot and converted into artificial flag-stones. Two hundred yards run of flag-stones can be turned out here in one day, and they are the hardest on the market. In making artificial stones, private firms often use brick dust and this does not resist so well as cement mixed with ground clinkers, kept three days under cover and then left to dry in the open-air for five weeks.

When the strike was over it was necessary to work both night and day before the accumulation of refuse could be dealt with, and this continued for several days. As each cart enters it is weighed and, according to the place it comes from, directed to the destructor or to the barges. A minute record is kept of all the work done. The destructor supplies heat for four boilers, and these provide power for the manufacture of the electricity needed in the city. Thus a cessation of the scavengers' work compromises other important services, and this gives a further insight into the disastrous consequences that would have ensued had the strike continued. Now, fortunately, all is restored to the normal conditions. But every class of the community has received an object-lesson of such a rough and emphatic character that it certainly will be long remembered.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Hospitals and Contributions from the City Council.

THE finance committee of the corporation has issued a report on the contributions made by the council to the local hospitals. Various hospitals and dispensaries have written to the education committee for contributions to their funds. Ultimately it was resolved that the matter of hospital contributions should be dealt with by the city council as a whole, acting through its finance committee. The contributions hitherto made annually by the various committees to the hospitals have been: gas committee, £200; electricity committee, £71; and tramways committee, £125. At various times payments have been sanctioned from the common fund to the amount of £152, making altogether £548. The education committee in return for services rendered by the medical staffs of three hospitals to scholars at certain schools contributes £20. Altogether the sum contributed to the hospitals is far too small, considering the large number of workmen employed by the corporation. There are 120,000 children in attendance at the schools, and the number of children treated at the hospitals has largely increased. It has now been decided that the gas committee shall contribute £250, the electricity committee £150, and the tramways committee £250, making a total of £650. To this will be added £850 from the city fund account, making a total of £1500 to be granted each year to the various hospitals of the city.

More Food Poisoning.

In THE LANCET of August 5th and 19th I reported a serious outbreak of ptomaine poisoning at Bacup. There has now been another, though less extensive, outbreak in the same district. From Crewe also is reported a mysterious outbreak of sickness in several families, in some cases the whole family being affected, supposed to be due to the eating of meat which caused severe ptomaine poisoning.

Efforts on Behalf of a Hospital.

Children's pageants have recently been organised in various towns as a means of raising money on behalf of the local hospital. The Women's Guild of Service arranged, on behalf of St. Mary's Hospitals, a great procession on Oct. 13th, representing 26 tableaux. Hundreds of keen collectors were provided with boxes to collect from the spectators the much-needed money. Last year the Working Women's Campaign raised £1026 in aid of St. Mary's Hospitals, and this, with other contributions, enabled the new buildings in Oxford-road to be completed and opened.

Spitting on Tramcars.

The corporation has at last prosecuted three persons who were guilty of this abominable practice. It is to be hoped that everything possible will be done in future to extirpate a habit so unhygienic, disgusting, and uncleanly. There is still much work for the corporation officials to do in this direction.

Death of Captain G. S. Nickerson, R.A.M.C.

The death is announced of Captain G. S. Nickerson, R.A.M.C., Governor of the Sennar Province of Egypt, at the age of 38, as the result of a fall from his horse. Captain Nickerson, like his younger brother, Major W. H. S. Nickerson, R.A.M.C., was educated at the Manchester Grammar School and at the Owens College Medical School. In other obituary notices some confusion has arisen. It was Major W. H. S. Nickerson who served in the South African war and received the Victoria Cross for his gallant conduct at Wakkerstroom on April 20th, 1900. Captain G. S. Nickerson, whose death is now deplored, was the eldest son of the Rev. D. Nickerson, M.A., vicar of Newton-on-Ouse, Yorks. He graduated at the University of Manchester as Bachelor of Medicine and Bachelor of Surgery in 1896, and in the following year obtained the diploma of Public Health. Before entering the Army Medical Service he held a surgical appointment at the Stockport Infirmary.

Oct. 23rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Medical Service in Liverpool.

ON Sunday, Oct. 15th, the annual medical service for St. Luke's Day was held at St. Luke's Church. The preacher was the Lord Bishop of London. The church, which seats 850 people, was filled to its utmost capacity. Inside, the sight was very picturesque, members of the medical profession in academic costume and officers and men of the Royal Army Medical Corps (T.) lending a pleasing variety to the scene. A procession comprising members of the profession (of both sexes) was formed at the west end of the church. The Lord Bishop of Liverpool read the lesson, the clergy taking part in the service being the Archdeacon of Liverpool and the Rev. W. Webster of the Liverpool College. The collection, which was on behalf of the British Medical Benevolent Fund, realised £57 3*s.* 1*d.*

Bequests to Liverpool Hospitals.

By the recent demise of Miss Willox, sister of the late Sir John Willox, M.P., the following charities will largely benefit by the terms of the will: £10,000 to the Liverpool Royal Infirmary, £10,000 to the Royal Southern Hospital, £10,000 to the Stanley Hospital, and £10,000 to the Liverpool Sanatorium for Consumption, Delamere Forest. The last-named bequest is to be known as the "Lady Willox Endowment Fund." £10,000 have also been bequeathed to the Newspaper Press Fund, London, to be invested more particularly for the founding of pensions or annuities for the benefit of incapacitated or indigent members. The late Sir John Willox was a distinguished member of the press.

Lancashire Sanitary Inspectors' Proposal: A Contemplated "Health Sunday."

The North-Western Centre of the Sanitary Inspectors' Association held its monthly meeting at the School of Hygiene on Oct. 14th. The members, who assembled from all parts of Lancashire, decided to recommend the General Council to consider the advisability of instituting an annual "Health Sunday" in every town and village throughout Great Britain. It was considered that by this means the question of public health would be prominently placed before the country. Mr. Francis Vacher, formerly medical officer of health to the Cheshire County Council and President of the association, subsequently addressed the members on "the position of women in regard to public sanitary work."

Oct. 23rd.

MEDICAL MAGISTRATE.—Dr. Benjamin Arthur Richmond of Rotherhithe has been added to the Commission of the Peace for the County of London.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol General Hospital.

AT a meeting of the election committee of the Bristol General Hospital Mr. George Parker, M.A., M.D. Cantab., M.R.C.S. Eng., was re-elected honorary physician for a further period of ten years, Mr. Newman Neild, M.B., Ch.B. Vict., M.R.C.P. Lond., M.R.C.S. Eng., was re-appointed honorary assistant physician for another term of ten years, and Mr. Frank Gower Bergin, L.R.C.P. Lond., M.R.C.S. Eng., was re-elected skiagraphist for a period of ten years. Mr. Joseph Storrs Fry, President of the institution, referred to the great loss involved in the death of Mr. C. B. Hare, and moved a resolution embodying a message of sympathy to his brother. This was seconded by Mr. Herbert Baker, the chairman, and supported on behalf of the honorary staff by Mr. Robert Lansdown, who spoke of Mr. Hare's courtesy and kindness to himself and his colleagues. At the memorial service at St. Mary Redcliffe the hospital was very fully represented by many members of the committee and of the medical, nursing, and clerical staff.

The Bristol Medico-Chirurgical Society.

The opening meeting of the 1911–12 session was devoted, as usual, to the presidential address, the presentation of the annual reports, and the election of officers. The society, having been rendered homeless by the migration of the medical library to different premises, met for the first time in the physiological lecture-theatre of the University. Among those present was Sir Isambard Owen, Vice-Chancellor of the University, who is an honorary member. The incoming president, Mr. C. A. Morton, senior surgeon to the General Hospital and professor of surgery to the University, gave an interesting address on the modern surgery of malignant disease, referring to the wide extent of the modern operative field and making special mention of his experience in the excision of rectal growths by the abdomino-perineal method. In supporting a vote of thanks, Mr. N. C. Dobson remarked that he had given a presidential address before the society 20 years before on the same topic. The secretary's report was fairly satisfactory from the financial point of view. The membership of the society is now 168. The librarian's report showed that the library, which is shared by the society with the University, contains 21,929 volumes and receives 249 periodicals. The removal to fresh premises has made it necessary to re-catalogue the whole library.

The Movement against Tuberculosis in Bristol.

The Bristol city council has decided to make the notification of pulmonary tuberculosis compulsory. The establishment of a tuberculosis "dispensary" along the lines of the Edinburgh and Paddington models is almost definitely decided upon. It will be supported, in part at any rate, by voluntary subscriptions, and it is hoped that it will be purely consultative in character, no patients being admitted to treatment, except at the instance of a qualified practitioner. The local profession has promised support to the scheme if it is conducted on these lines.

Milk and Tuberculosis.

At the last meeting of the Plymouth borough council it was decided "that a sum not exceeding £10 be expended in an investigation of the condition of milk sold in Plymouth as regards tubercular infection." One of the members remarked that it was the commencement of what was hoped would be a thorough testing of the milk-supply of the town.

Radio-activity and the Bath Mineral Waters.

The baths committee of the Bath corporation, at its meeting held on Oct. 20th, decided that experiments should be made to afford information as to the best methods of employing radium emanations and the relations between radio-activity and temperature of baths and the drinking cure. Its value in different forms of inhalation is also to be investigated.

The Research Defence Society.

A meeting of the Devon Branch of the Research Defence Society was held in Torquay last week. There was a good attendance, and Professor R. F. C. Leith of Birmingham gave an interesting lecture, illustrated with lantern slides, on "Some of the Gains Obtained by Experiments upon Animals."

Poliomyelitis in Cornwall.

At the quarterly meeting of the Cornwall county sanitary committee the medical officer of health (Dr. R. Burnet) reported that up to the present 37 cases of acute anterior poliomyelitis had been notified in Cornwall since the beginning of August. The chairman, the Hon. John Boscawen, said that Dr. Burnet had worked admirably over the matter. It was regrettable that his son had contracted the disease.

The Sewerage of St. Ives (Cornwall).

A Local Government Board inquiry was held at St. Ives on Oct. 18th in regard to the application of the local council for permission to borrow £1400 for the purpose of sewerage works for the town.

Oct. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Colonel W. P. Warburton, C.S.I., I.M.S.

ALTHOUGH it had been known in Edinburgh during the past few weeks that Colonel Warburton's health was very unsatisfactory, the news of his death on Oct. 18th came as a shock. Only a few weeks previously an assemblage of medical friends met to take leave of Colonel and Mrs. Warburton, and at that time there seemed the probability of years of life before him. Colonel Warburton was a native of Prince Edward Island, where he received his early education. He was a graduate in medicine of the University of Edinburgh. In 1866 he entered the Indian Medical Service, in which for over 30 years he had a distinguished career. Among the posts held by Colonel Warburton in India were those of medical officer to the native State of Kapurthala, a post which he occupied for 17 years. For short periods he acted as principal medical officer of the Assam military district, and of the military districts of Bandelkhand and Narbada. For four years he was Inspector-General of Civil Hospitals of the North-Western Provinces of Oudh, and later, during the absence of the Director-General, he officiated for three months as Director-General of the Indian Medical Service. At the time of his retirement from the service in 1899 he was honorary surgeon to the Viceroy, and had conferred on him the distinction of the C.S.I. At the end of 1899 Colonel Warburton succeeded Major-General Lithgow in the office of medical superintendent of the Edinburgh Royal Infirmary, from which post he retired at the end of July of this year. On Oct. 21st a simple and impressive funeral service was conducted in the chapel of the Edinburgh Royal Infirmary at noon by the infirmary chaplain, the Rev. Mr. Henderson. It was attended by the managers and by the medical, nursing, and other staffs. The board was represented by Sir Joseph Fayrer, Bart.

Opening of the Royal Medical Society.

Professor Robert Saundby of Birmingham opened the 135th session of the Royal Medical Society on Oct. 20th with an address which was chiefly reminiscent of his connexion with the society when a student. He recalled with pleasure the difference in the debates held in that hall from those of other medical societies. The student was not then afraid to express his opinions, irrespective of whom he might assail. Professor Saundby gave interesting details of the various professors under whom he had worked when studying in Edinburgh—e.g., Christison, Hughes Bennett, Saunders, Laycock, and others. He was always disappointed now with the performances of students at their final examinations. They seemed to have forgotten most of their early studies, and appeared not to appreciate the bearing of chemistry, physiology, and other sciences on clinical medicine. He thought, perhaps, that there was too much teaching and too little thinking on the part of the student. As soon as one examination was over the student very often forgot all he had mastered. He thought that the organisation of teaching was better in Edinburgh than in England; the teachers in the former were better paid and so were able to adopt teaching as their profession, while in England the

necessity for private practice often took up so much of the teachers' time that scant attention was paid to hospital work. In the large cities of England there was ample clinical material, and the medical students ought to do better. He deplored the fact that valuable clinical posts in the hospitals of Birmingham went vacant owing to lack of zeal on the part of Birmingham students. As to the prospects of those entering the medical profession he was sanguine; he did not think it was an overcrowded or ill-paid profession. There was no other profession in which the pecuniary prospects were better; a young doctor could at once earn a living, and there were so many avenues to success—army, navy, and colonial services, lunacy, public health, and so forth. The chances of success for the general practitioner were, however, not so good as they had been, but the opportunities for specialism were greater. Owing to frequent change of residence the bond between patient and practitioner was not so strong as formerly, and thus the young practitioner had now a larger share of practice than was the case formerly. He regretted that medical men did not form partnerships more often, as the advantages were very great. On the motion of Professor Crum Brown, a very hearty vote of thanks was awarded to Professor Saundby.

Dr. Angus Fraser's Retirement.

At the half-yearly meeting of the Aberdeen University Council, held on Oct. 14th, it was unanimously resolved to inscribe the following paragraph in the minutes of the Council: "That the General Council desires to place on record its great regret at the retirement of Dr. Angus Fraser, and its cordial appreciation of his services to the University and to the cause of medical education, in particular as acting as one of the Council's assessors to the University Court, 1889 to 1911." Dr. Ashley Mackintosh, in moving that the foregoing paragraph should be included in the minutes of the Council, said that it was difficult to overstate the services Dr. Fraser had rendered, more particularly to the medical school. Dr. Mackintosh thought he expressed the feeling of all when he said that no teacher in the University had a more sincere place in the hearts and memories of his pupils than Dr. Fraser. Years ago he had heard the opinion expressed by one of their most distinguished alumni, the late Sir James Anderson, that one of the best teachers he had ever come across was Dr. Angus Fraser. Dr. Fraser also had the entire confidence of the medical profession in the North of Scotland. Since 1889 he had held office as an assessor unopposed, and surely no stronger proof of the value of his services could be given. Nobody wished more heartily than the Council that his health might be restored, and that he might be spared for many years to enjoy the rest and retrospect of work well done.

Presentation to Professor D. MacEwan.

At a large and representative meeting of directors, past and present, at Dundee Royal Infirmary, on Oct. 5th, Professor MacEwan was made the recipient of a handsome silver tea service and a large silver tray bearing the inscription:—"Presented by the present and past members of the Board of Directors to Professor David MacEwan, M.D., in recognition of his valued services during 43 years to the Dundee Royal Infirmary. September, 1911." Professor MacEwan was joint house surgeon from July, 1868, to February, 1870. He was first appointed visiting surgeon in 1874, and continued in that position until he resigned on Sept. 30th, 1911. The presentation was made by Mr. T. H. Smith, who spoke in cordial terms of the personal qualities and great services of Professor MacEwan to the infirmary.

Oct. 23th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Heating and Cleaning of Primary Schools.

IN the annual report of the Commissioners of National Education, issued a few days ago, it is stated that at length the Treasury has agreed to provide certain funds to aid in the heating of the school-houses and the cleansing of out-offices. The Commissioners had asked for a grant sufficient to provide for the daily cleaning and weekly charing of the school premises, in addition to the heating of the school-rooms. The amount promised, however, would only provide half the necessary amount; the other half must be provided locally. Hitherto there was no general provision for heating and cleaning, and the expenses had often to be borne by the teacher. In country districts the children carried fuel in the form of peat to school with them.

Old People in Asylums.

At the last meeting of the committee of the Richmond Asylum the medical superintendent, Mr. Donelan, lodged a protest against the reception of senile patients in asylums. He held that these people should be provided for in workhouses. Their admission to asylum wards tended to "distort" statistics and to give a false idea of the relative proportion of recoveries and incurable cases. Moreover, it was cruel to their relatives to put on such patients the stigma of lunacy. The collection of accurate statistics, however, is hardly the dominating object of an asylum.

Medical Substitutes' Fees.

A point of some interest in regard to substitutes for medical officers has recently cropped up in the Edenderry Union. Dr. Waters was appointed temporary medical officer for the Johnstown Dispensary District by the relieving officer, who informed him that the remuneration would be a guinea a day. Dr. Waters acted for 12 days, and submitted a bill to the guardians for 12 guineas. The board refused to pay on the ground that the settled remuneration for medical substitutes in the Edenderry Union was £4 4*s.* per week. On Dr. Waters stating that the relieving officer had specifically engaged him at a guinea per day, the matter was referred to the Local Government Board. The latter replied that a relieving officer had no power to "bargain" with a doctor, and therefore the guardians were not justified in paying the rate of remuneration arranged. This point was decided a few years ago by the Lord Chief Baron, who held that the relieving officer had no authority to pledge the credit of the guardians further than any scale which they might have adopted. The remedy for the medical man is to hold the relieving officer personally liable.

Royal College of Physicians.

The annual meeting of the College was held on St. Luke's Day, when Dr. J. Hawtrey Benson was re-elected President, Dr. G. Peacocke Vice-President, and Dr. T. P. C. Kirkpatrick registrar. The annual dinner was held in the evening.

Typhus Fever in Belfast.

On Oct. 19th the officials of the Public Health Department of Belfast removed to the union hospital and to Purdysburn infectious diseases hospital four cases of typhus fever. The patients are closely related: three are from one street and the fourth—intimately associated with the others—is from an adjacent place. Seven "contacts" were disinfected and are being watched. The cases are mild.

The Water Famine in Belfast.

From October, 1910, to September, 1911, inclusive, only 28·75 inches of rain fell, while for the same 12 months during the previous driest years on record—1887 and 1893—the rainfall was 30·77 and 33·15 inches respectively, the average yearly rainfall for the city being 34·57. The present drought is, therefore, very exceptional. A leading citizen of Belfast, who has a thorough knowledge of engineering, recommends in the press a "stand-by" or "emergency" scheme for providing a temporary supply of water of some eight million gallons per day by pumping the water of Lough Neagh into the existing Stoneyford works (a distance of a little over six miles), from which it could be conveyed into Belfast. The Water Commissioners do not favour this plan; they seem to rely upon rain coming as usual, and they intend to apply for powers in the coming session of Parliament to enable them to construct a reservoir—which should long ago have been done—in the Mourne Mountains. Fortunately, the weather has altered and rain has at last come.

The King Edward Memorial in Belfast.

At a meeting of the executive committee of this scheme, held on Oct. 19th, it was reported that the fund, which had reached £17,570, would be kept open a little longer to increase it, if possible, to £20,000. The plans for the new building at the Royal Victoria Hospital, the form decided on for the memorial, will then be considered.

County Antrim Infirmary.

A three-day bazaar, with the object of increasing the funds of the County Antrim Infirmary, was opened in Lisburn on

Oct. 19th by the Countess of Aberdeen, who was accompanied by the Lord Lieutenant. Lady Aberdeen gave some most interesting recollections regarding her family's connexion with the district, and referred to her great-uncle, Dr. W. Thompson, who did the first ovariotomy in Ulster, and was for many years surgeon to the County Antrim Infirmary, and whose widow endowed the well-known Hospital for Incurables. Their Excellencies inspected the infirmary, visited the bazaar, and the Thompson Memorial Home for Incurables.

Oct. 24th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Congresses.

IN addition to the Surgical Congress, of which I wrote in some detail last week, the second congress of the French Pædiatric Association took place on Oct. 6th and 7th under the presidency of Dr. Comby. Little's disease, which was the subject of various reports was first considered. The second question was infant tuberculosis. The meeting decided on holding the first International Congress of Pædiatry at Paris in October of next year. The Obstetrical Society of France held its meeting from Oct. 5th to 7th, at which reports were presented on the pathogeny and treatment of puerperal eclampsia. The French Association of Urology held its meeting also from Oct. 5th to 7th, when reports were presented on non-hydatid cysts of the liver, and on non-hydatid cysts of the kidney.

A Chemist's Mistake.

Last month a Paris chemist dispensed for a patient a solution of corrosive sublimate in mistake for a soothing draught. Immediately after the departure of the purchaser the chemist discovered his error, but, ignorant of the name or address of his customer, he was unable to communicate with her. In order to prevent, or at least to minimise, the consequences of his mistake, the chemist at once inserted a warning notice in the newspapers, hoping that his customer would read it before making use of the draught. The warning, however, came too late, for she had drunk a portion of the draught on the day of purchase. She was saved by the intervention of a medical man, but she was nevertheless ill for a fortnight. On the pharmacist indemnifying her the action she had instituted was withdrawn.

The Paris Water-supply.

The question of the Paris water-supply, to which I have referred several times this year, has engrossed the attention of hygienists all the summer. The Commission of Surveillance of the Bureau of Hygiene met on Oct. 19th to investigate the present alarming condition. In the poorer quarters of Paris a serious epidemic of typhoid fever is raging, and the most urgent measures have become necessary to safeguard the public health. During the summer, in order to provide a sufficient water-supply, as I stated in THE LANCET of August 12th, 35,000 cubic metres daily of water from the Marne were distributed by the existing pipes, after disinfection with sodium hypochlorite. It now appears that this sterilising process was inadequate, so that the water which was turned into the reservoirs of Ménilmontant, Montsouris, and Charonne has contaminated all the pipes in these quarters, as is shown by the charts of typhoid fever cases at present notified in all these parts of Paris. Further, M. Hanriot, of the Academy of Medicine, declares that he has found not only chlorine in the dangerous waters but also sulphuric acid. Investigation has disclosed the fact that it had been found requisite to treat the waters of the Vanne by sodium sulphate to neutralise the excess of chlorine. This was the more necessary in that these waters were not, like the 35,000 cubic metres of water from the Marne during the month of August, mingled with 200,000 cubic metres of spring water. Moreover, this mode of sterilisation, efficacious enough against the bacillus coli, is inadequate against Eberth's bacillus. Parisians have therefore been officially recommended to boil their water, a recommendation especially necessary in the poorer quarters particularly attacked. The wealthier quarters have little to fear, for they have always taken all necessary precautions to sterilise their water, and, moreover, there the habit of drinking mineral waters is almost universal.

The Radium Palace.

Madame Curie has asked M. Ménot, the architect of the Sorbonne, who is building the Radium Palace on the site of the former Convent of Visitandines in the rue St. Jacques, to add a teaching laboratory. The original plans of the Palace contemplated only a research laboratory, to the cost of construction of which the Pasteur Institute undertook to contribute 400,000 francs and the University of Paris 280,000. The new laboratory desired by Madame Curie will not add more than some 40,000 francs to the expense. It will accommodate 40 students. This additional subvention will be sought from the University of Paris.

Oct. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Temperance Movement in Austria.

AT a meeting of the Austrian anti-alcohol societies held recently in Graz it was remarked that the proportion of medical members was increasing considerably, an important fact both as an indication of the favour with which the temperance movement was regarded in well-informed quarters, and also on account of the influence which such practitioners exercised over their patients. Another notable feature was the circumstance that numerous college and university students have joined the ranks of the anti-alcoholists within the last two years. For those who know that beer-drinking is (or rather used to be) one of the chief relaxations of the German students, this fact is more significant than a whole volume on the subject. A third and also a very important item in the discussions was the attention paid by many speakers to the influencing of children in favour of total abstinence. In fact, a large proportion of the papers dealt with the effects of alcohol on children. Dr. Weiss of Vienna, as well as Professor Kassowitz, pointed out how the breast feeding of infants was interfered with by alcoholic indulgence on the part of the mother; the latter also denounced the use of alcohol as a tonic for children under 14 years of age. Frau Fröhlich, who read a paper on Alcoholism in Children under Six Years of Age, said that both in rural districts and in industrial centres infants were often given some alcoholic tincture, or even more or less diluted brandy, as a hypnotic, to ensure a quiet night for the hard-working parents. Beer-drinking was quite common at a very early age in Bohemian and Silesian villages, since the parents had no clear ideas as to the harmful effects of this habit. Frau Masaryk gave an account of an inquiry which she had made with reference to the use of alcoholic beverages by school-children. She described the facts supplied to her from reliable sources as fearful. In certain districts there was not a single boy over 12 years who had not been intoxicated at least once. Even in the larger towns boys and even girls were regularly given an evening drink from their parents' beer glass, whilst in the wine districts the daily consumption of light wine by children amounted on an average to a pint per head. Dr. Schweighofer of Salzburg delivered an address on the Effects of Parental Alcoholism as Manifested in the Offspring, illustrating his remarks by a series of lantern pictures. He maintained that alcohol rather than syphilis was mainly responsible for the increase of mental disease amongst our modern population. He therefore urged the necessity of restricting the manufacture and sale of alcoholic beverages, since the income derived from this source by the State was more than spent in combating its evil effects in the forms of crime and illness.

Illness of Professor von Neusser.

The numerous friends of that eminent physician, Professor von Neusser, will learn with regret that he has had to undergo a severe operation for nephrolithiasis and subsequent hydronephrosis. He is reported to be doing well, but still his condition is such as to cause a good deal of anxiety to his family. It may be mentioned that the diagnosis of his illness was made by himself.

Disorderly Scenes in the Anatomical Institute.

Owing to their constantly increasing number the students

in the anatomical institute have had to put up with a great deal of discomfort in the course of their work. The accommodation for those engaged in dissection has become so inadequate that students have had to wait their turn for weeks and weeks; and the conveniences for washing have been altogether insufficient. Some idea of the congestion may be formed from the fact that 500 students are working at a time with only 200 chairs at their disposal, and only two hot-water pipes in use. At the recent opening of the winter term the students organised a noisy demonstration, at the same time assuring the professor (Dr. Tandler) that this form of protest was not directed against him but against the administration of the clinical institutes—in fact, against the Government. The professor acknowledged the reality of their grievances and volunteered to go at the head of a deputation to the Dean of the University and afterwards to the Ministry of Education in order to present a request for the necessary funds for the required improvements. This was agreed to, and after some delay the Government consented to grant 30,000 kronen in order to increase the number of seats and to provide certain important apparatus. One of the chief subjects of complaint, however, will be very difficult to remedy. This is the insufficiency of the ventilation, for owing to the situation of the institute in one of the busiest main thoroughfares the windows of the dissecting rooms and laboratories cannot be opened as frequently as would be desirable.

Oct. 23rd.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

The Harvey Lecture by Dr. Simon Flexner.

Dr. Simon Flexner, of the Rockefeller Institute, in delivering one of the lectures of the Harvey Society recently, took as his subject the local specific therapy of infections. At the Rockefeller Institute, he said, experimental influenzal meningitis had been induced in monkeys and had been successfully treated by a serum produced by Dr. Waldstein. Monkeys even in an advanced stage of the disease had recovered under local treatment. Pneumococcal meningitis also had been induced in the monkey, but up to the present time pneumococcal serum had given very poor results. The micro-organism of acute poliomyelitis was so minute as to be invisible. It was localised in the central nervous system, the paralysis being secondary. The most probable means of treating the disease successfully was by local injection. Dr. Flexner considered urotropin of little use in developed cases, though perhaps of some value as a preventive measure. In the treatment of infantile paralysis, if any success was to be looked for, early treatment was essential. Work was being pursued at the institute with the view of producing effective serums for the treatment of dangerous local infections, and there was reason to hope that their efforts might ultimately be crowned with success.

The Milk-supply Problem in New York.

At the New York Academy of Medicine, in the Section of Pædiatrics, the milk question as it relates in certain of its aspects to infant mortality was recently discussed. The Chief Health Commissioner, Dr. Lederle, asked the members of the Academy to support the Health Department in its efforts to obtain an appropriation from the Board of Estimate to enable it to open 70 milk stations in Greater New York. He said that at least 1200 infants had been saved in the past nine months by the improved quality of the milk supplied and by the campaign of education. The milk problem, he said, had become a great economic problem, and it was impossible in a city of the size of New York, where 1,600,000 quarts of milk were used daily, to have each quart pure enough for infant feeding. Such a course was neither requisite nor economical. To solve the problem he had prepared a schedule subdividing the milk-supply into three classes—for infants and children, for adults, and for cooking purposes.

New York's Lowest Death-rate.

There has been a substantial decrease of the death-rate of the city for the first nine months of the year. The death-rate for this period was 15·56 per 1000, as against 16·27 per 1000 for the corresponding period of 1910. Up to Sept. 30th of this year 11,733 infants under 1 year have died from all causes, as against 12,920 for the period ending Sept. 30th, 1910, giving death-rates of 124·6 and 142·3 per 1000 respectively.

Conditions in Factories of New York State.

Dr. Charles D. Graham-Rogers, of the State Labour Department, recently described to the Wagner-Smith Factory Investigating Commission the conditions menacing the lives and health of factory workers. He stated that he alone was "the entire Bureau of Medical Inspection" for the factories of the State, and that he was utterly powerless, under the present law, to cope with the evil conditions he found and could merely report them with recommendations for remedial measures. Insanitary conditions, he said, prevailed throughout the factories of the State. Children were employed in phosphorus match factories, packing matches in boxes, although the law permitted their employment only in stacking the boxes. He recommended the absolute exclusion of women and children from match factories and the absolute prohibition of the use of yellow phosphorus. Among other recommendations made were the following: (1) compulsory dust removal and ventilation; (2) medical examination of employees; (3) instruction in industrial hygiene in schools; (4) the establishment of a division of industrial hygiene composed of medical men, biologists, and chemists; and (5) the prohibition of work in cellars.

Renaming of Blackwell's Island.

Blackwell's Island, which was for many years the seat of the city asylums for the insane, ordinary and criminal, with its old buildings, now enlarged and improved, has been given over to the hospitals of the Department of Charities. That body has, therefore, decided to change the name of the island to Hospital Park, the commissioner pointing out that the self-respect of the present inmates is safeguarded by changing the name with its connotations of crime and insanity.

The Budget Exhibit.

The Budget Exhibit is an annual object-lesson to the taxpayers of New York, showing them how the local taxes are expended. The departments of health and charity naturally occupy considerable space and attract much attention from the 15,000 daily visitors. An interesting exhibit is a model milk station for children, in which is a huge map of Manhattan borough, showing every infant death of the past year marked with a black dot. Moving pictures display various sections of the overcrowded East Side.

Abolition of the Public Drinking Cup.

The regulations regarding individual drinking cups in public places have led to occasional ludicrous results. The Pennsylvania Railroad supplied paraffin individual cups for its patrons, and the newly landed immigrants, confusing these with the gelatin cones in which penny ice-creams are sold, attempted to devour them. Some of the smaller hotels supply the paraffin cups in slot machines. The New York Public Library has installed a kind of fountain which throws a stream of water directly into the air, which the thirsty bend over and drink.

A "Christian Science" Home.

The "Christian Science" adherents, who seem to have dropped out of the public eye considerably since the death of Mrs. Eddy, have at length heeded the reproach that they have never done anything for the sick poor, and the first "Christian Science" Home of the State of New York has been incorporated.

Illicit Drug-Selling.

Five arrests were made recently in one day for the illegal sale of opium, the Federal excise officers finding over £300 worth of the drug prepared for smoking. This smoking opium is said to be made from the ordinary solid extract, mixed with lactose and the residuum found in the interior of the opium pipe after its use for some time, which is known as *yen shi*. A drachm of this mixture is sold in a small tin can, or "shell," for 50 cents (2*s*.). Such a shell furnishes the usual daily dose: when "cooked" *secundum artem* it makes about a dozen "pills."

New York State Hospital for Incipient Tuberculosis.

Bronze tablets were unveiled recently in the two new pavilions of the State Hospital for Incipient Tuberculosis in

the Adirondacks. These pavilions, erected in memory of Dr. John H. Pryor of Buffalo and Dr. Willis G. Macdonald of Albany, double the capacity of the institution and cost in themselves over £40,000; they will reduce a waiting list of 150 to 10 or 12. There are now an administration building and four connected pavilions, with 516 acres of farm and forest land, valued in all at over £100,000. Patients live in the open air the year round, and the institution claims to cure from 76 to 84 per cent. of all incipient cases.

Hookworm Disease in California.

The California State Board of Health has asked for the coöperation of the United States Public Health and Marine Hospital Service in regard to the prevalence of hookworm disease in the State. It has been shown that about 25 per cent. of immigrants into the State are infected; also that many of the deep gold miners are suffering from the disease. Dr. Charles W. Stiles, of the Public Health Service, is at present investigating this disease in Texas.

Oct. 17th.

Obituary.

ALFRED PETER HILLIER, M.D., C.M. EDIN.,

MEMBER OF PARLIAMENT FOR NORTH HERTS

THE announcement of the death of Dr. A. P. Hillier, which took place in tragic circumstances at his residence in Eccleston-square on Oct. 24th, will be received with regret by members of the medical profession. In the House of Commons he was an active worker, whose speeches were listened to with attention. His vigorous criticisms of the National Insurance Bill during the past session of Parliament will be remembered by our readers.

Dr. Hillier, who was born in 1858, was the son of Mr. P. Playne Hillier of Shortwood, Gloucestershire. He graduated M.B., C.M. at the University of Edinburgh in 1882, having previously taken the B.A. degree of Cape University in 1877. In 1884 he proceeded to the M.D. degree. In 1878–79 he served as a trooper with the Colonial Forces in the Kaffir War, obtaining a medal and clasp. Subsequently he commenced practice at East London, Cape Colony, and later was appointed resident surgeon to the Kimberley Hospital, afterwards entering into partnership with Dr. (now Sir Starr) Jameson. Politics, however, appealed to him strongly, and on going to Johannesburg in 1893, in which year he was elected President of the South African Medical Congress, he took an active part in Transvaal affairs. As a prominent member of the Reform Committee at the time of the Jameson Raid he was for some time confined in Pretoria Gaol, being released in 1896 on the payment of a fine of £2000. In the following year he returned to England. In 1899 he was one of the delegates of the National Association for the Prevention of Consumption to the Berlin Tuberculosis Congress. He was consulting physician to the London Open-air Sanatorium and was also a councillor of the Royal Colonial Institute. His interest in public affairs won him from the active practice of his profession, and he devoted himself more and more to politics. In 1900 he unsuccessfully contested Stockport, and in 1906 he was rejected by South Bedfordshire, but in January, 1910, he was the successful candidate for the Hitchin Division of Hertfordshire, standing in the Unionist interest.

Dr. Hillier was joint editor of *Tuberculosis*. In 1900 he published "Tuberculosis: its Nature, Prevention, and Treatment, with Special Reference to the Open-air Treatment of Phthisis," and in 1903 the "Prevention of Consumption." His political writings included "Raid and Reform," which was published in 1897; "South African Studies," published in 1900; and the "Commonweal, or the Federal System of Political Economy," published in 1909. He also contributed articles on South Africa to the Encyclopædia Britannica, and was the author of the "Antiquity of Man in South Africa and Evolution." Dr. Hillier married in 1885 a daughter of Mr. F. B. Brown of Queenstown, Cape Colony, whom he leaves with one son and two daughters.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Richard Schulz, formerly *oberarzt* of the Ducal Hospital in Brunswick, aged 63.—Dr. Ludwig Bauer, *docent* of hygiene in the Stuttgart Technical School, aged 47.—Dr. Emil Emmert, *docent* of ophthalmology in the University of Berne. He was the son of the late Dr. Karl Emmert, professor of forensic medicine, and published various papers on ophthalmological topics, and also on the subject of school hygiene. He was 66 years of age.—Dr. Blatin, formerly professor of physiology in the Clermont Medical School.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in October the following candidates passed in the subjects indicated:—

Surgery.—E. E. Allen (Sections I. and II.), Royal Free Hospital; E. G. Brisco-Owen (Section I.), Cardiff and Royal Free Hospital; F. G. Norbury (Section II.), Glasgow; and G. S. Richardson (Section II.), Leeds.
Medicine.—E. E. Allen (Section II.), Royal Free Hospital.
Forensic Medicine.—E. E. Allen, Royal Free Hospital; H. N. Eccles, Guy's Hospital; E. B. Keen, Charing Cross Hospital; and F. C. Shone, University College Hospital.
Midwifery.—E. E. Allen, Royal Free Hospital; L. M. Ladell, London Hospital; H. Rimington, St. Bartholomew's Hospital; F. C. Shone, University College Hospital; and H. G. Steel and W. H. Vincent, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. E. Allen, F. G. Norbury, and G. S. Richardson.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Kulbs, who recently came from Kiel to be Professor His's First Assistant in the Medical Clinic, has been granted the title of Professor.—*Cracow:* Dr. Johann Mazurkiewicz of Lemberg has been recognised as *privat-docent* of Psychology.—*Göttingen:* Dr. Bernhard Zoeppritz has been recognised as *privat-docent* of Midwifery and Gynæcology; and Dr. Oswald Loeb, formerly of Berne and Basle, as *privat-docent* of Pharmacology.—*Greifswald:* Dr. Pels-Leusden, now in charge of the surgical side of the Berlin Charité Policlinic, has been offered the chair of Surgery in succession to Dr. F. König, who has gone to Marburg.—*Innsbruck:* Dr. Hans von Haberer of Vienna has been appointed to the chair of Surgery, in succession to Dr. Schloffer, who is migrating to Prague. Dr. Hans Rabl, extraordinary professor in Vienna, has been offered the chair of Histology and Embryology.—*Moscow:* Dr. S. Golovin of Odessa has been appointed to the chair of Ophthalmology.—*Naples:* Dr. Battaglia has been recognised as *privat docent* of Anatomy and Pathological Histology; Dr. G. Spinetti as *privat-docent* of Operative Medicine; and Dr. De Sandro and Dr. E. Ciaramelli as *privat-docenten* of Internal Pathology.—*Rome:* Dr. S. Tini and Dr. F. Scordo have been recognised as *privat-docenten* of Internal Pathology; Dr. L. Dominici and Dr. S. Puglisi Allegra as *privat-docenten* of External Pathology; Dr. A. Mendicini, Dr. G. Bianconi, and Dr. G. Impallomeni as *privat-docenten* of Orthopædic Surgery.—*Turin:* Dr. E. Calamida and Dr. C. Mantelli have been recognised as *privat-docenten* of External Pathology, Dr. E. Mani as *privat-docent* of Ophthalmology, and Dr. Bertolotti as *privat-docent* of Physio-therapeutics.—*Vienna:* Dr. Otto Poetzl has been recognised as *privat-docent* of Psychology and Neurology.

KING'S COLLEGE (UNIVERSITY OF LONDON).—A course of four advanced lectures in Physiology will be delivered in the Physiological Laboratory, King's College, London, by Dr. F. S. Locke on Energetics, at 4.30 P.M., on the following Mondays: Nov. 13th, 20th, 27th, and Dec. 4th, 1911. These lectures are free to all members of King's College, London, to all internal students of the University of London, to all medical students in London, and to all medical men on presentation of their cards.

ROYAL DENTAL HOSPITAL OF LONDON.—The annual dinner of the staff and past and present students will be held on Friday, Nov. 24th, at the Hôtel Métropole (Whitehall Rooms), under the presidency of Mr. Walter Harrison. Those who desire to be present are requested to communicate with the Dean. The medical committee will be "At Home" to all old students of the hospital on the following day from 2.30 to 5 P.M., when the various departments of the hospital and school will be open, and specimens

and cases of interest, &c., will be shown by the members of the staff and lecturers.

LITERARY INTELLIGENCE. — The University of London Press announce for early publication: "Infectious Diseases and their Preventive Treatment" by Edward Seaton, M.D., consulting medical officer, Surrey County Council.

FINE FOR WATERING MILK.—A farmer was fined £20 and costs, or three months' hard labour, by the Bristol magistrates last week for selling milk containing 27·65 per cent. of added water. He had been fined before on two occasions.

DEATH OF A CENTENARIAN.—The death occurred recently at Upper Snailham Farm, Icklesham, East Sussex, of Mrs. Sarah Ann Carter, who had attained the great age of 102. She was born at Northiam, and had resided in the vicinity all her life. At the time of her death Mrs. Carter had 50 grandchildren, 110 great grandchildren, and 13 great great grandchildren.

DEATH OF DR. WILLIAM LANG.—At Southwick, Sussex, on Oct. 13th, the death occurred of Dr. William Lang in his 71st year. Studying at Glasgow University he graduated C.M. with honours in 1863 and proceeded to his doctorate in the same year. For some time he was resident assistant medical officer at Town's Hospital and the City Lunatic Asylum, Glasgow, but subsequently he settled in Grenada, West Indies, where he was health officer for the port of Grenville. He was living in retirement at Southwick.

CHELSEA CLINICAL SOCIETY.—The opening meeting of the fifteenth session of the Chelsea Clinical Society was held on Oct. 17th at St. George's Hospital Medical School. The retiring President, Dr. T. W. Parkinson, most generously presented the society with a presidential badge. The President, Dr. J. A. Mansell Moullin, gave the opening address on the subject of "Hysterectomy and its Influence upon Gynæcological Surgery of the Present Day." In future the society will hold its meetings in the club-rooms of St. George's Hospital Medical School, which have very kindly been placed at the disposal of the society by the authorities and executive officers of the hospital.

ST. BARTHOLOMEW'S HOSPITAL WOMEN'S GUILD. —A well-attended meeting was held in the Great Hall of St. Bartholomew's Hospital on Monday, Oct. 23rd, at the invitation of Lord and Lady Sandhurst, to inaugurate a women's guild for the hospital. A short account of a similar guild at Guy's Hospital was given by Mrs. Lauriston Shaw, and after speeches by Lord Sandhurst and Dr. Norman Moore resolutions were passed forming the guild and electing the first committee and officers. The objects of the guild are to provide clothes for the use of necessitous patients in the wards and on their discharge from the hospital, and to take up any other work in connexion with the hospital which from time to time may commend itself to a general meeting with the sanction and approval of the treasurer and almoners.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

PARLIAMENT has re-assembled after its autumn holiday, and the Government has taken steps to secure the passage of the National Insurance Bill into law before the end of the year. On Wednesday, Oct. 25th, the Prime Minister submitted to the House of Commons a closure motion allocating time to its further discussion. After protests from the Opposition, a time-table was adopted by which the future proceedings on the Bill are to be regulated. Sixteen Parliamentary days have been allocated to the consideration in committee of the clauses and schedules of the invalidity portion of the Bill which have not yet been reviewed by the House of Commons. Seventeen clauses were discussed before the House rose for the holidays. The unemployment portion of the Bill has been referred to a Grand Committee. Five Parliamentary days are to be given to the report stage. The contention of the Government is that this time-table will afford adequate opportunities for the discussion of the various fresh questions which arise on the Bill.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London, W. LONGMANS, GREEN, AND CO., New York.

International Medical Monographs. General Editors: Dr. Leonard Hill, F.R.S., and Dr. William Bulloch. The Mechanical Factors of Digestion. By Walter B. Cannon, A.M., M.D., George Higginson Professor of Physiology, Harvard University. Price 10*s.* 6*d.* net.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

FLINT.—On Oct. 14th, at Cliff House, Buxton, Derbyshire, the wife of Thomas Buxton Flint, M.R.C.S., L.R.C.P., of a daughter.

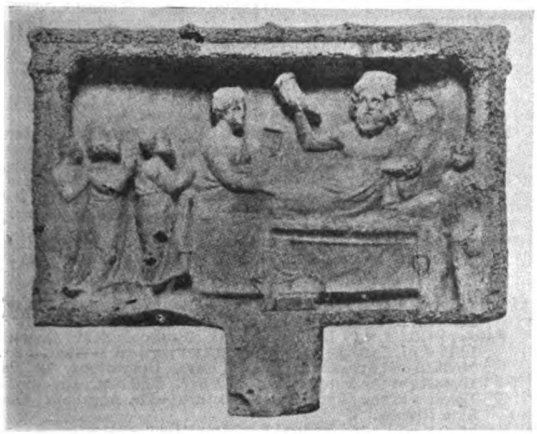
GRIFFIN.—On Oct. 19th, at Baldock, Herts, the wife of John P. Griffin, M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGES.

GRAHAM LITTLE—KAUFFMANN-KENDALL.—On Oct. 21st, Ernest Gordon Graham Little, M.D., B.A., F.R.C.P., to Sara Helen Kauffmann-Kendall, daughter of the late Maurice and of Mrs. Kauffmann-Kendall, of Chester-terrace, Regent's Park.

DEATHS.

BREAKEY.—On Oct. 21st, at Carlisle Mansions, Victoria-street, London, John Breakey, M.D., R.N., Inspector-General of Hospitals and Fleets (retired).



SIMPSON.—At 52, Queen-street, Edinburgh, on Oct. 25th, Dame Margaret Stewart Barbour, wife of Emeritus Professor Sir Alexander Russell Simpson, M.D. No flowers, by request.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A NEW GREEK MONUMENT TO ASKLEPIOS AND HYGIEIA.

AMONG the numerous specimens of Greek sculpture and the bronzes and statuettes that have for several years been in course of recovery from the wreck of a Roman ship discovered by the sponge fishers off Mahdia, in Tunis, has recently been found an Attic relief, of which we present a reproduction of a photograph. It is the latest obtained of a series of reliefs depicting the sacred banquet offered to Asklepios and Hygieia and is carved in marble. The scene shows six persons partly inside or in front of some pillared edifice, perhaps one of the porticos of the deity's temple, where he was supposed to appear to and heal the faithful. At the extreme right, and in front

of one of the pillars, is a young Neocoros bearing some kind of patera. To the left are a man, woman, and youth or girl, the last of the three being partly outside the shrine. The centre of the stele display Asklepios and Hygieia in greater proportionate size than the other four figures. The deity is half reclining upon a couch, the upper part of his body nude. He is about to drink from a large rhyton held in his right hand, whilst the left holds a saucer containing some kind of food. His eyes are lifted heavenward. He is bearded, and his abundant locks of hair support the calathos, a vase-shaped basket used as a headdress. Hygieia is seated upon a sort of dais, and is shown in profile with her face turned towards her father. Her hair is ornamentally gathered up to the head, leaving the neck bare. She wears a tunic and mantle. In one hand she holds a receptacle, doubtless for incense, and her feet are supported upon a stool. Before the couch of Asklepios is a table bearing the ritual meat or cakes for the banquet. Although no direct information has been derivable from the wreck as to whence its contents were obtained, archæologists have been able to show, from inscribed stones that were on board and from the date of certain objects, that the vessel left Greece soon after the sack of Athens, and of the Piraeus, by Sylla. Several objects among the relics are known to have come from the navy yard there, where the sacred galleys, once part of the Athenian fleet, were housed; and classic authors especially speak of the booty the Roman legions took from the Piraeus. At this port there was an Asklepieion frequented by mariners, and four stela, somewhat similar to this one from Mahdia, have been found upon its site. There can be but little doubt that this relief also comes from the Piræus, because the sunken galley has among its cargo inscriptions carried off from temples standing there. Moreover, the workmanship is not quite so good as was generally considered appropriate for the Asklepieion at Athens, so there is every reason to consider that it was taken from the shrine of the god of healing at the arsenal, from which emporium also were derived two bronze prow ornaments belonging to the ancient galleys housed there, which have also been found at Mahdia.

HEALTH OF THE GOLD COAST.

THE official report, just issued, on the Blue Book of the Gold Coast Colony for the year 1910, estimates the European population at 1830. The general population of the colony and its dependencies was returned in 1901 as 1,696,695, but, partly owing to reluctance on the part of the natives to be enumerated and partly to defective organisation, the Census was incomplete. There is no compulsory registration of births and deaths, but in the principal towns the burials are registered. The death-rate per 1000 amongst Europeans in 1910 was 27·18, as compared with 12·82 in the previous year, and the invaliding rate per 1000 was 43·75, as compared with 38·48. The causes of invaliding amongst European officials were: Malarial fever, 6; anæmia, 5; blackwater fever, 3; neurasthenia, 3; gastritis, 2; heart disease, 2; various, 11. Among non-officials: Malarial fever, 12; blackwater fever, 6; anæmia, 3; gastritis, 4; various, 17. No means exist of obtaining accurate statistics as regards the health of the natives, but from the data available it would appear that the sickness-rate for 1910 was less satisfactory than that of the previous year. In the early part of 1910 there were 10 cases of yellow fever, 9 of which were fatal, amongst Europeans in Seccondee. During the year 50 cases of sleeping sickness were treated in the different hospitals, and 11 deaths were recorded; the disease was more prevalent in Ashanti than in the colony. Glossina palpalis is reported to be present in most districts, and the possibility of an outbreak of sleeping sickness on the Gold Coast is now recognised, and efforts are being made to cope with the situation. In Ashanti there were several outbreaks of small-pox. The number of vaccinations performed throughout the Gold Coast was 25,590, of which 14,060 were successful. During the year 43,943 cases of disease were treated, of which 271 proved fatal. The most prevalent maladies were dysentery, malarial fever, rheumatism, venereal diseases, diseases of the eye and of the respiratory system, abscesses, skin diseases, and parasitic diseases. New hospitals have been completed at Tarquah, Akuse, and Winnebah, and a special fly-proof hospital has been built at Anum in the Volta district for the treatment of sleeping sickness and observation of suspects. The older hospitals still maintained are those at Accra, Seccondee, Cape Coast, Axim, Saltpond, Elmina, Quittah, and Addah.

A WARNING.

To the Editor of THE LANCET.

SIR,—It would, I think, be well to insert the following warning in your columns. A tall, well-developed man between 30 and 40 years of age, with ginger-coloured hair, and giving the name of Fitzgerald, called to see me the other day at 9.15 A.M. As my consulting-room was not available at the moment he was shown into the drawing-room. He was fairly well dressed and had a tweed cap. The story was that he was a doctor from Australia, had been in bad company the previous night, where he was robbed of watch and all his money. He had been drinking heavily the previous day. After he left a silver table-bell was missing. Information has been laid at the Marylebone police station.

I am, Sir, yours faithfully,

Weymouth-street, W. CHAS. W. CHAPMAN.

A SURGICAL RECORD.

ACCORDING to the *Allgemeine Medizinische Central-Zeitung* Professor Dr. Poppert recently performed his 2000th operation for the removal of gall-stones in the surgical clinic of the Giessen Hospital. This is supposed to be a record number—at all events for European hospitals.

CHRISTMAS GIFTS TO CRIPPLED CHILDREN.

Sir William Treloar writes to remind our readers of the annual distribution of hampers and clothing to poor crippled children of the metropolis which he has organised each Christmas for so many years past. Donations will be welcomed by him at 69, Ludgate Hill, London, E.C.

HYGIENE FOR BOYS.

A Naval Surgeon who wishes to give an hour's talk of a practical nature to boys of about 16 on their first joining the Navy, asks for information as to a small book or pamphlet likely to assist him in the matter; also whether suitable lantern slides are available. The intention is not to "talk morality," but to teach the boys to have respect for their bodies by learning something about them and their working.

MERCK'S ANNUAL REPORT.

WE have received an advance copy of this annual report, which contains a valuable record of progressive pharmaceutical chemistry and therapeutics. It gives a thorough presentation of the developments which have been announced during the 12 months under review. The present volume (Vol. XXIV.) comprises 380 pages of literary matter, and a feature on this occasion is the large space devoted to the therapeutic use of the cacodylates. We always find Merck's Annual Reports a source of useful and reliable information. Copies of the current report may be obtained from E. Merck, 16, Jewry-street, London, E.C.

A. M. Z.—1. The partnership would be responsible for the rent of the telephone. 2. The partnership, being the tenant of the groom's cottage, appears to be liable for the rates as well as for the rent.

ERRATUM.—Messrs. A. and M. Zimmermann point out that in our notice of "Atophan" in our last issue, the words "carbolic acid" were used when "carbonic acid" was intended.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for October and November, 1911:—

April-October.—Rome Exhibition (United Italy's Jubilee).
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th-Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opened June 14th closed Oct. 16th).
,, 12th-Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
September-November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 26th-28th (Rome).—Congress of the Italian Society of Laryngology, Otology, and Rhinology.
,, 31st-Nov. 4th (London, Royal Horticultural Hall).—Twenty-second Universal Cookery and Food Exhibition.
October (Paris).—First Congress of the International Medical Association for the Prevention of War.
Nov. 1st (opens) (Turin).—International Exhibition of Hygiene.
,, 1st-14th (London).—"The Englishwoman" Exhibition of Arts and Handicrafts.
,, 3rd-11th (London, Olympia).—Tenth International Motor Exhibition.
,, 9th-11th (Cape Town).—Congress of the South African Branch of the Royal Sanitary Institute.
,, 10th-25th (Manchester).—Smoke Abatement Exhibition.
,, 14th and 15th (Vienna).—Jubilee of Union of Austrian Dental Surgeons.
,, 21st-23rd (Montreal).—Canadian Public Health Association (First Annual Meeting).
November (Rome).—Fourth International Congress of Physical Education.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

FRIDAY.

LARYNGOLOGICAL SECTION (Hon. Secretaries—W. H. Kelson, Dan McKenzie), at 11, Chandos-street, W.: at 5 P.M.

Cases

Will be shown by Dr. StClair Thomson, Dr. Kelson, and others.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—J. H. Targett, W. W. H. Tate), at 11, Chandos-street, W.: at 8 P.M.

Dr. P. Cole: Broad Ligament Cyst of Müllerian Origin.
Dr. Lockyer and Mr. Turner: Cancer of Uterus and Ovary subsequent to Double Salpingectomy.
Dr. Hubert Roberts: Tuberculosis of Uterus.
Dr. Barris: Urinary Organs in Pyelo-nephritis of Pregnancy.
Dr. Macnaughton-Jones: (1) Rare Books from Prof. Klein (Munich): (2) Ovarian Fibroma with Cancer of Uterus; (3) Ovarian Cystoma of Unusual Size.
Dr. Inglis Parsons: Fibroma of Uterus with Cancer of Cervix.
Dr. Banister: Unusual Case of Chorion-epithelioma.

Short Communication:

Dr. T. Copeland Savage (Auckland, N.Z.): A Case of Full-term Extra-uterine Gestation. Laparotomy during Spurious Labour. Recovery of Mother with Living Child.

(N.B.—Please note that this Meeting of the Section will be held on FRIDAY.)

SECTION OF ANÆSTHETICS (Hon. Secretaries—Mrs. Dickinson Berry, H. J. Scharlieb): at 8.30 P.M.

Reports on Two Cases of Death Under Anæsthesia.

Short Communications:

Dr. W. J. McCardie Notes on Cases showing Some of the After-effects of Chloroform.
Dr. J. F. W. Silk: Case of Pleurisy and Bronchitis after Open Ether.
Mr. Rowland Collum: Notes on a Troublesome Dental Case.
Mr. Bellamy Gardner: The Use of a Mouth Prop and Tongue Clip as a System of Anæsthesia.

(Members are invited to give a record of any interesting cases that have occurred in their practice.)

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Clinical Cases.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Clinical Evening.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. J. E. R. McDonagh: Clinique (Skin). 5.15 P.M., Lecture:—Dr. L. H. Pegler: On Some Nervous Affections of the Pharynx and Larynx, including Functional Aphonia.
TUESDAY.—4 P.M., Dr. W. J. Fenton: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. G. Stevens: Unusual and Excessive Hæmorrhage at Puberty and the Menopause.
WEDNESDAY.—4 P.M., Mr. L. H. McGavin: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. Jones: The General Medical Treatment of Early Cases of Insanity.
THURSDAY.—4 P.M., Mr. M. White: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. A. Wylie, Treatment of Middle Ear Disease by Hot Medicated Air.
FRIDAY.—4 P.M., Mr. L. Paton: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Abdominal Drainage.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Davis: Diseases of the Ear. (Lecture III.)
WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Lloyd Williams: Etiology-Pathology and the Prevention and Treatment of Caries of the Teeth.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Armour: Surgical Anatomy of Inguinal and Femoral Herniæ.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Disease.
SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 2.15 P.M., Special Lecture:—Dr. F. Taylor: Acute Abdominal Pain.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Mr. Walton: The Diagnosis of Upper Abdominal Lesions.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting) 4.30 P.M., Demonstration:—Dr. G. N. Meachen: Selected Skin Cases.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. J. Atkinson: Nose.
FRIDAY.—3.30 P.M., Lecture:—Mr. J. G. French: Some Points in Chronic Middle Ear Suppuration.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Mr. S. Scott: Peripheral Mechanism of Sound Perception.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. Ormerod: Cases from the Ward.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. C. Wall: Asthma and Nasal Disease.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Bacteriology of the Skin.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Syphilis: History and Primary Invasi n (Constitutional and Local).—Eruption, Erythematous (I., Macular; II., Maculo-Papular).

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. E. B. Leech: The Medical Aspect of Gall-stones (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

A Clinical Lecture
ON
ACUTE IRITIS.

Delivered at the West London Post-Graduate College on August 30th, 1911,

BY N. BISHOP HARMAN, M.A., M.B. CANTAB., F.R.C.S. ENG.,

ASSISTANT OPHTHALMIC SURGEON, WEST LONDON HOSPITAL; OPHTHALMIC SURGEON, BELGRAVE HOSPITAL FOR CHILDREN; SOMETIME EXAMINER IN ANATOMY, CAMBRIDGE UNIVERSITY.

GENTLEMEN,—The condition chosen for the subject of this lecture is one which must be of interest to every one of you. But it is one upon which it is scarcely possible to say anything new, certainly as regards that most essential part of our work—treatment. My aim will be, therefore, to bring the appearances of this inflammation and its treatment vividly before your mind, so that iritis shall become, as it were, a foe well known in form and feature, one whose presence you will discover with facility, so that having recognised it you may attack it and lay it with all speed and decision.

SOME OLD-TIME WORKS.

This inflammation has been, from some point of view or other, the subject of innumerable disquisitions, both in monographs, papers, and in text-books, and some of these are well worth your study. There is stored up in our libraries a wealth of old-time critical observation, made by men who sought out the truth when aids to diagnosis were far less numerous than now, and as a consequence their minds were the more intent upon elaborating those physical signs which were patent to sight and touch, just those which you can as readily perceive when you are far from a laboratory such as you are accustomed to in a well-equipped clinical school.

To cite only a few such works. You could not do better than spend an evening with the *De Iritide* of Fredericus Augustus ab Ammon, published in 1839; it is written in Latin, yet to anyone who read Cæsar's Commentaries with tolerable facility in his school days the understanding of this work will not be difficult. Then the section on Iritis in the Practical Treatise of Diseases of the Eye by William Mackenzie, of the date 1830, is well worth study; but you must remember that at this date iritis and glaucoma were not well differentiated, so that under "arthritic iritis" we find described what we now know to be something quite different from iritis, and which we call simple or acute glaucoma. Then there is not a man in any of the British services who should fail to read the two little books of John Veteh, sometime a British army surgeon. The one, "An Account of the Ophthalmia which has Appeared in England since the Return of the British Army from Egypt," and the other, "On the Diseases of the Eye," published in 1820. They are small in compass, but weighty in thought and observation, and you will find there a brilliant piece of generalisation upon iritis to which I shall refer later.

Then as regards treatment, one half-hour's reading of a paper by T. Pridgin Teale, jun. (in the Transactions of the Ophthalmological Society of the United Kingdom of 1866), in which he describes his experiments into the separate value of the numerous prescriptions surgeons were wont to fire blunderbuss fashion at their patients, will tell you all that is really worth knowing on the subject.

Not one of you can afford to be without a practical acquaintance with this inflammation and its treatment, and a comparison of your personal observations with the observations of those who led the way into the knowledge of to-day will prove an exercise of the greatest value.

REMARKS ON DIAGNOSIS.

In this lecture I propose we should confine our attention to acute iritis, and exclude from our consideration iritis due to injury, from sympathetic inflammation, and those forms of subacute and chronic inflammation associated with cyclitis and changes in Descemet's membrane.

To the untrained, and therefore unperceiving, eye of the casual onlooker any violent inflammation of the eye looks much the same, and the sensations complained of by the patient may seem indistinguishable. Acute iritis, acute glaucoma, and acute conjunctivitis all produce an intense redness of the white of the eyes, all reduce the clearness of vision, and all cause pain more or less severe. But to you must come the sharpness of vision and keenness of understanding which shall see beyond this general likeness and recognise essential points of difference, for upon your diagnosis must follow prompt and vigorous treatment, which, if it be appropriate, will result in a speedy relief to the patient, but if it be inappropriate will result in disaster and perhaps blindness. Treatment that is a sure cure for iritis is certain blindness for glaucoma, and what is good for a conjunctivitis is unmitigated evil for both iritis and glaucoma.

THE SCHEME OF THE IRIS.

For a proper understanding of the state of the iris in acute inflammation, and of the rationale of the treatment thereof, a knowledge of the structure of this most beautiful of organs is essential. I do not propose to enter into details of anatomy you can find in any good text-book, but let me attempt to give you a graphic idea of it.

Conceive it as a curtain set up to divide the eye into two unequal parts. The basis of the curtain is a loose skeleton or spongework of connective tissue; it is complete save for a circular hole piercing its middle. The skeleton forms a scaffolding upon which are hung a series of muscles, blood-vessels, and nerves. Of muscles two sets; one to close the mouth of the central hole, and another to drag it widely open. Of vessels plenty, arranged in two rings, the larger at the attachment of the curtain and a smaller around the hole, with numerous communications between them. Of nerves an intricate plexus, following the lines of the muscles and vessels, and intimately communicating with both. The curtain is painted behind with a layer of rich pigment, which penetrates more or less into the substance, and in some subjects even to the face of the curtain, so as to produce an infinite variety of colours and markings.

Such a curtain must needs be very "lively"; it presents infinite possibilities of movement, and a delicate susceptibility to influences, good or bad, that may arise from the state of its owner. The looseness of the spongework that forms its basis and the richness of its blood-supply suggest how readily it will swell in states of inflammation; the complexity of its nerves, and their intimate association with those others both within and without the eyeball, tell how severe must be the pain of such inflammations; and lastly, the thinness and incompleteness of its covering tell how certainly inflammatory fluids within its mesh will escape to the surface as exudates, which, if they be coagulable, will glue the curtain to whatever it touches. Were this curtain a thing of mechanics of large and handleable size, and were we to substitute some other fluid for the blood, you would have no hesitation to press back the curtain and empty its mesh of its superabundant fluid, just as you would squeeze a sponge and prevent its sticky surface adhering to whatever it might be in contact with. That is the whole secret of the treatment of iritis, as we shall see in the following striking case.

A TEXTUAL CASE.

A man, aged 44, was seen at the West London Hospital just a year ago with all the symptoms of a most intense iritis in the left eye. He said that the eye began to be red two days previously, and since then on account of the intense pain he had had no sleep. The eyelids were swollen and blotchy, tears coursed down his cheek, and he turned his head away from the light. When the eyelids were parted the conjunctiva was seen to be a fiery red, there was no pus or muco-pus, and, except for a little froth due to an excessive secretion from the Meibomian glands which had collected about the inner canthus and in the lacus lacrymalis, the conjunctiva was shining and bright. The cornea was slightly hazy, and within the anterior chamber and filling full two-thirds of its cavity was a jelly-like mass. The mass was conterminous with the rim of the cornea towards the nasal and lower borders, but elsewhere it was free and presented a smooth rounded edge. It was semi-transparent, so that through it could be seen a contracted and irregular pupil partly blocked with white material. The whole of the iris had a swollen and dirty appearance, in marked contrast to the clean bright iris of the healthy eye.

The eye was exquisitely tender to the touch, and the tension of the globe fuller than that of the healthy side.

On examining the conjunctiva closely it was evident that every blood-vessel was engorged with blood, their finest ramifications and anastomoses could be traced out; but besides these vessels those deep to the conjunctiva which run in the episcleral tissue and those that perforate the sclera were equally engorged. The distinction of these two sets of vessels was clear: there was an obvious difference in depth; there were differences in colour, for the surface vessels were brick-red and the deeper ones of a dusky red colour; but the main distinction could be made certain by gently moving the conjunctiva from side to side by means of pressure through the eyelid, then the conjunctival vessels were seen to ride over the fixed scleral vessels. Tracing these deeper vessels we could see how engorged they were at the points of penetration into the sclera to reach the ciliary region and how prominent were the fine vessels which form a close network about the limbus of the cornea. The features of this engorgement of the deeper vessels pointed to an inflammation of the structures within the eye, and particularly of the ciliary body and the iris with which these vessels are directly associated. The engorgement of the conjunctival vessels then appeared in its true light, merely a coincident effect of the intensity of an inflammation which, as by a spreading wave, upheaved all those parts contiguous with it.

Similarly, examining that part of the iris not covered by the jelly-like mass within the anterior chamber, we could see upon its surface points of bright red colour, and these when examined with the corneal loupe resolved themselves into a number of small blood-vessels which bulged from the surface of the iris by reason of their engorgement with blood.

Next in order for solution came the problem of the jelly-like mass within the anterior chamber. Its shape and apparent solidity suggested at once a comparison to the size, shape, and consistency of the crystalline lens, and I have heard it said that such a condition was once mistaken for a dislocated lens. A further examination of the iris was enough to dispel any possible thought that an accidental dislocation of the lens might account for this case. It was clear the iris was well supported behind, for it was not tremulous, neither did it appear to be depressed backwards towards the posterior chamber. Nothing but the lens in its proper place could support the iris so exactly as this iris was supported, so the jelly-like mass must be some adventitious product. Despite its appearance of structure and solidity it could be nothing else than a coagulum, a clot of exudate poured out from the inflamed iris and ciliary body. The disturbance of these organs had altered the character of the aqueous, so that instead of a mildly albuminous fluid it had become rich in fibrin and albuminous coagulable albumins, with the result that it had clotted and made a cast of the anterior chamber, and the clot after its kind had shrunk away from its mould to produce the singular appearance of this picture.

That the symptoms of this man's condition were correctly read was evident, for the effects of the treatment, based upon the diagnosis, were such that in three days' time the coagulum had completely disappeared, the pupil was widely dilated, the exudate upon the lens capsule gone, and there was naught to tell how nearly the inflamed iris had been glued down to the lens save one lump of brown uveal pigment on the lens and a corresponding gap in the uveal edge of the iris.

To complete the history of this case, the man acknowledged having suffered an attack of gonorrhœal urethritis 25 years ago and to having acute rheumatism of his knees shortly after. He had had iritis 12 years ago. He denied contracting syphilis, and the Wassermann reaction examined by Dr. Julius Bernstein was negative.

Six months after the severe attack I have detailed his left eye became painful, there was marked injection of the ciliary vessels, and when the iris was dilated the earliest physical signs of a cyclitis could be detected in the vitreous close behind the iris. By examining this with the direct ophthalmoscope and a high convex lens the centre of the vitreous had a properly clear and unclouded character, but the peripheral region close to the ciliary body was clouded by reason of numberless fine dots; in this change could be seen the effects of an altered secretion from the inflamed ciliary body.

THE SIGNS OF IRITIS, GLAUCOMA, AND CONJUNCTIVITIS CONTRASTED.

Now the iritis in the case I have narrated was one of great severity, the physical signs of iritis were writ large, and in almost dramatic fashion. You will not always get the diagnosis written so boldly on every case you see, yet the signs will be the same, and as recognisable on careful search. Let us go over the more important symptoms, and compare them with those of diseases with which confusion is most likely to arise, glaucoma and conjunctivitis. Conjunctivitis is particularly an affection of the young, acute iritis of adults, and glaucoma of the elders, yet each may occur at any age, and in some points their symptoms may coincide.

The character of the pupil I put first. There is no one condition by which a distinction between iritis, glaucoma, and conjunctivitis may be made; but if you were confined to one point for your diagnosis, the pupil should be your choice. In iritis of even mild degree it is altered in shape; as compared with the other eye it is smaller and less round. When we shade the eye it does not dilate well, and when again exposed to the light it does not contract promptly; its reaction is sluggish, or if the iritis has been of some days duration the pupil may be fixed. These symptoms are due, first, to the inertia of a membrane engorged with blood and exudates; and secondly, and particularly, because the pupillary margin is gummed to the lens capsule by the sticky exudates of inflammation, or fixed by the succeeding adhesions. It is these that cause the irregularity in the contour of the pupil, and they can be seen quite plainly when we attempt to dilate the pupil. By contrast, in conjunctivitis the pupil is unaffected, its reactions are brisk or even excessive. In glaucoma the pupil suffers from the increased intra-ocular pressure, which causes a partial paralysis of the sphincter so that the pupil is larger than that on the normal side, its contour oval, and its reactions lost.

The altered colour of the iris is striking in acute iritis; the blue eye becomes dirty green and the brown becomes muddy. These effects are due to the lymph that exudes on the surface and to the increased vascularity. Similar effects are seen in glaucoma, but not in conjunctivitis.

The character of the injection of the vessels over the surface of the globe is not a sign upon which to put great reliance. In iritis and glaucoma the disturbance is so great as not only to cause engorgement of the scleral vessels, but to involve those of the conjunctiva and eyelids. In severe conjunctivitis the converse may be seen, the conjunctival injection spreading to the scleral vessels. But in cases of lesser severity one could scarcely fail to suspect irritation of the iris and ciliary body when there was present a delicate circumcorneal blush without conjunctival injection.

Pain is present in all three of these acute inflammations. But the character of it as a diagnostic sign may be rather unreliable. Patients differ so greatly in their sensations and in their mode of expressing them. Yet there are broad differences in their sensations. In conjunctivitis their complaint is usually of something under the lids—dirt, sand, or even glass. This is because the nerve terminals in their irritation translate their feelings in terms of their usual warning—dust in the eye! In iritis there is pain within the eyeball, and referred pain over the brow and root of the nose, for the iris gains its nerve-supply from branches of the nasal branch of the ophthalmic division of the fifth. In acute glaucoma the pain is more intense, both in the eye itself and in referred pain, so that it may involve the areas of the first, the second, and even the third divisions of the fifth nerve; it may be so severe as to cause sickness or actual vomiting.

Discharge is, of course, characteristic of conjunctivitis, and it is absent from iritis and glaucoma—there is only excess of tears. But one must beware of mistaking excessive Meibomian secretion for discharge; it can be seen in almost any tearful state as a fine white froth along the edges of the lids and at the inner canthus.

The transparency of the cornea is usually but little affected in the early stages of acute iritis. In conjunctivitis it is clear unless infective ulcers occur. In glaucoma it is "steamy," fluid is driven into it by the excessive intra-ocular pressure.

The depth of the anterior chamber varies so much with age that much stress must not be laid upon it. A very shallow chamber undoubtedly points to glaucoma, although the reverse may occur. In conjunctivitis it should not vary

from the unaffected eye. In iritis it may be normal or slightly deeper, and perhaps filled with turbid contents or even a coagulum, such as in the case described.

Vision is affected in all three conditions, least in conjunctivitis, most in glaucoma. In conjunctivitis the disburbance varies with the chemosis, presence of ulcers, and the character of the discharge. In by far the most cases it is only disturbed by the particles of mucus or pus that stick or float over the surface of the cornea. In iritis vision is clouded by the exudates on the lens capsule. In glaucoma it is rapidly lost by pressure on the optic nerve head, but before this occurs and blindness sets in the steaminess of the cornea gives rise to certain subjective symptoms which anyone can see for himself by breathing on a sheet of glass and quickly looking at a candle flame through the steamed medium.

After we have looked at the eye from every possible point of view we may venture to handle it. By palpation we can determine its sensitiveness and its tension. The globe is tender to pressure in acute iritis, particularly in the ciliary region; it is exquisitely tender in all its parts in glaucoma. By way of contrast, the sensibility of the cornea to light surface contact, such as is produced by the touch of a wisp of cotton-wool, is lost in glaucoma, for the internal pressure of the eye renders the fine terminals anæsthetic. In iritis the cornea does not loose sensibility. Palpation elicits no tenderness in conjunctivitis.

Next as regards the tension of the globe, high tension is the characteristic of glaucoma, and in acute cases the hardness of the eyeball is unmistakable. But it must be borne in mind that a moderate increase in tension is by no means rare in acute iritis; the muddy fibrinous aqueous of inflammation passes through the drainage area with difficulty, its escape is delayed, so that tension within the globe is raised.

Looking over these notes of differential diagnosis one may remark that there are not a few troublesome "ifs" and "buts" that spoil otherwise prime points of distinction. This is true. One symptom does not make a disease any more than one swallow a summer. Yet if there be one symptom upon which I would lay stress it is upon the character of the pupil. It is normal in acute conjunctivitis, small and sluggish in acute iritis, wide and paralytic in acute glaucoma. As I have said, too much care cannot be expended in examining its character with the naked eye, or better with oblique illumination and a good binocular magnifying glass. The glaucomatous pupil can scarcely be confounded with the normal or iritic pupil. But it is possible for difficulty to arise in the case of a pupil contracted by iritis and one that is small by reason of age. Elderly people naturally have small pupils with sluggish reactions, and in such patients a conjunctivitis may be mistaken for an iritis. The systematic examination of the healthy eye of a patient before the affected eye is looked at will insure against many mistakes, and particularly against such an one as this. But there are some cases in which the point can only be determined by the instillation of a drop of homatropine so as to dilate the pupil; an iritis would be disclosed by irregular dilatation; a full round pupil would exclude iritis.

THE CAUSES OF ACUTE IRITIS.

I propose to say very little on this head—not because there is little interest in its discussion, but because by so doing I wish to impress upon you the fact that the primary cause of the inflammation has little or no bearing upon the direct treatment of the inflammation.

Venereal disease accounts for the majority, possibly more than 75 per cent. of all cases. Secondary syphilis accounts for fully half. The coincidence of sore throat, a typical body rash, and iritis is not uncommon, and it is indisputable evidence of a common origin for the three symptoms. It is the only variety of acute iritis which bears anything like a special feature, for in this there are frequently seen small nodules of yellow colour spotted with pink vessels along the pupillary border; these are granulomata, and at their site the inflammation is most intense and massive synechiæ most likely to occur.

Next in order of frequency come gonorrhœal and rheumatic iritis. For the present it is not possible to separate the two. There has always been a conflict of opinion as to how far one or other of these affections determined iritis. Of the causal relation of gonorrhœa to iritis in certain subjects there can be small room for doubt. Vetch appears to have been the first to have seen what might be called the gonorrhœal syndrome. There is his remarkable observation of the liability to the succession in the same subject of gonorrhœal urethritis, purulent ophthalmia, arthritis, and iritis, an observation which Mackenzie, writing 20 years later, stigmatised contemptuously as a "notion" and "a good example of a hasty generalisation in regard to diseases between which no other relation than that of concurrence has been pointed out." The conclusion of Vetch is sure enough to-day, at least so far as the urethritis, purulent ophthalmia, and arthritis are concerned, only we cannot definitely prove the iritis, for the organism recoverable from each of the others of the syndrome has not been recovered in it.

Rheumatic iritis has been scouted by some. It is remarkable how rarely we see iritis in the subjects of acute rheumatic fever; and never an iritis during its progress or convalescence, notwithstanding the frequency of inflammations of other serous membranes. Recently Paine and Poynton have shown that the injection into rabbits of the micrococcus rheumaticus can produce iritis with exudation into the anterior chamber, and from these cases they have recovered the organism. I have seen some cases of these animal infections produced by other workers; there was no doubt of the iritis, but the massive purulent exudate in the anterior chamber suggested rather a pyæmia than an ordinary acute iritis. At present the point cannot be determined, its interest is undeniable, but so far as the direct treatment of the iritis is concerned it does not matter in the least.

Then there remain a residuum of some few cases where iritis has occurred during, or closely after, acute fevers—e.g., malaria, typhoid, influenza, and even mumps; or subsequent to exposure to cold or undue strain. These cases are of milder type than that described above, but they are just as liable to produce synechiæ and endanger the vision. Of malarial iritis I have seen very few cases. One of these I remember well. The subject was a naval pensioner sent on to me with this diagnosis. He denied any venereal infection, but he acknowledged having been an in-patient of a naval hospital with swollen knees and hand-joints, for which the diagnosis "sequelæ of gonorrhœa" was written on his sheet! Of typhoid fever I saw more than enough when on service in the South African War, but in not one case did I see an acute iritis at any stage of the fever or of convalescence, nor did I hear of a case from any of my numerous fellow officers.

The determination of the origin of any given case of acute iritis is by no means easy. When syphilis, gonorrhœa, and rheumatism appear to be reasonably excluded, we naturally fall back upon the nearest untoward incident in the life of our patient as likely to be the determining factor. Considering the structure of the iris it would not be a matter for wonder if all these incidents did set up iritis, so that this inflammation were much more common than it is. But the remembrance of the number of folk in all kinds of states of life and nutrition who suffer these incidents with never a trace of iritis makes us wonder what are the primary causes of these rare cases. If an incident innocuous to the irides of most patients does become a determining excitant in these few, what underlying diathesis or vulnerability favoured the incident? These are speculations which you can pursue in your leisured moments: to follow them now would lengthen this lecture interminately.

THE TREATMENT OF ACUTE IRITIS.

An examination of ancient medical works will show that at different periods systems of pathology have exerted a profound influence upon the principles of treatment. At one period the fashion was all for local applications to an inflamed or sympathetic part; at yet another period the whole body was afflicted with a humour which flamed out in one spot, and the modification or dispersal of that humour could alone relieve the local inflammation. The same ideas are found in folk medicine to-day, and they are no more strange than the action of a learned physician of the eighteenth century, who records with much pride his disastrous treatment of an infant with ophthalmia neonatorum by physicking the mother.

In approaching a case of acute iritis it is well to take sides, not one, but both sides. First be a devotee of direct applications to the eye. Then, when you have set going all that you can on that score, turn about and become a devotee of

the humoral pathology. Let us call the first direct treatment, and the second indirect treatment, and consider these two sides.

Direct Treatment.

Reverting to our similitude of the sponge-like curtain of the iris, let us treat the iris as one would a spongy curtain loaded with sticky fluid and flopped upon the clear glass of the window. To leave the curtain thus would effectually close the window. We should certainly draw back the sodden curtain, and squeeze out the sticky fluid from its texture. We can do this very thing with an inflamed iris. In atropine we have a most effective drug to fling wide the pupil and fold back the iris. That action determined upon, how best can we use the drug? There is no better preparation than an ointment of the sulphate of atropine combined with hydrochlorate of cocaine, 2 per cent. of each, in equal parts of lanoline and vaseline. This is the most effective midriatic known. A small piece should be placed within the lower lid every hour for the first four hours, and then every two hours until the pupil is widely dilated. Later, the strength and the frequency of the application may be reduced to 1 per cent., night and morning. Taken at the outset, the worst case of iritis will react to this treatment, and to this alone; and both pain and injection will abate as the pupil dilates.

But we need not despise adjuvants to this essential treatment. Moist heat is a great reducer of pain and most comforting to the eye, so we employ relays of hot fomentations. Or in the worst cases, such as that of the man cited, we may blanch the region of the eye by withdrawing blood by leeches applied to the outer canthus, and in this way materially hasten the action of the atropine. The severity of the pain may be checked, at least temporarily, by instilling a 5 per cent. solution of dionine, a derivative of morphia, and to some extent the drug acts upon the blood and lymph circulations, but its effects are not constant.

To what length of time may this vigorous action be continued, it may be asked. So far as the atropine and fomentations are concerned, until the injection has declined. The fomentations *ad libitum*, but the atropine in just sufficient strength to keep the pupil open.

But if the pupil will not dilate by reason of adhesions, what then should be done? Here our action must be guided by the character of the adhesions. If they are tough and white, the result of an earlier attack, atropine is useless. We must rely upon fomentations and leeches to reduce the inflammation and then free the occluded pupil by a judicious iridectomy. If the synechiæ are brown or yellowish, and therefore recent, the full strength of the atropine should be employed for at least three days before the attempt to break them down is given up. In this matter practice differs. Bronner does not hesitate to release an adherent and inflamed iris by an immediate iridectomy. Elliot relies upon the reaction of subconjunctival injections of normal saline solution to secure the same result.

Indirect Treatment.

Now turning to the other side, we consider how we can attack the inflamed eye through the body. Part of this attack should be routine treatment in every case; part will vary as our diagnosis of the primary cause of the iritis varies.

In every case at the outset a smart purge should be given. The subjects of iritis nearly always have foul mouths and breath, and are constipated. Any drug that will give a free and watery stool will do, and to aid this plenty of water should be given with and after the draught. Absolute rest in bed in a dark room should be insisted upon, and alcohol and tobacco made taboo.

Lastly, in any case of which the origin is indeterminate or pending its determination an alterative is useful, and there is no better than the iodide of mercury—5 grains of iodide of potassium with a drachm of the liquor of perchloride of mercury. If the case be syphilitic it is first-rate treatment; if it be due to gonorrhœal rheumatism it is good—better than vaccine treatment; only if there be arthritis at the time salicylates or aceto-salicylic acid are better.

At this point your question will be on the use of salvarsan. Should this be injected in a case of indubitable syphilis? That depends. First, is the case bad enough to put the patient to this added discomfort and risk, seeing that without doubt simpler methods will speedily reduce the iritis? Secondly, is he fit enough to be subjected to the treatment, which is undoubtedly severe? The answers to both these points will be qualified by the presence or absence of other symptoms of syphilis; with evidence of the general activity of the poison the case for injection would be strong. But the final choice will rest with the patient, to whom the advantages and disadvantages of the proposition must be fairly put.

In conclusion, no matter how superlative a mode of general treatment may be evolved now or at some future date, general treatment can never oust atropine from the first, the middle, and the last place in our first line of offence against iritis. That was the finding of Teale's paper of 1866, and it remains true to-day.

Two Lectures
ON
THE TREATMENT OF DIABETES MELLITUS

Delivered at St. George's Hospital

BY EDMUND I. SPRIGGS, M.D. LOND.,
F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL.

LECTURE II.[1]

GENTLEMEN,—I propose to-day to speak of the treatment of cases of diabetes mellitus in which *diacetic acid is present in the urine*, and, at the risk of repetition, must remind you that the presence of fatty acids in the urine shows that the amount of carbohydrate which can be burnt by the tissues has fallen so low that fat has to be oxidised with great rapidity to supply the needs of the body, with the result that its combustion is incomplete. It is also probable that a certain amount of carbohydrate is essential in civilised man to furnish food to the cells which metabolise the fat. The presence of fatty acids in the tissues would be fatal did not the body possess means of neutralising the excess of acid. This is done to some extent by giving up bases such as calcium, magnesium, potassium, and sodium from the tissues, but chiefly by providing the base ammonia, which, instead of leaving the body as urea, renders the acid harmless by forming an ammonium salt with it, and is passed out in that form. In some cases very large quantities of ammonia may be excreted every day, and when no alkali is being prescribed the amount of ammonia in the urine may be taken as a general guide to the severity of the acidosis.

TREATMENT OF CASES WITH DIACETURIA.

In this condition, the objects of treatment are, first, to maintain nutrition; secondly, to reduce the rate of the metabolism of fat to its former level by increasing the amount of carbohydrate which can be assimilated; and, thirdly, to supply alkali to neutralise the excess of fatty acids produced. The essential feature of the dietetic treatment of diabetes is, of course, exactly the same whether diacetic acid is present in the urine or not—namely, so to order the diet that a maximum amount of carbohydrate may be assimilated. The difference between the two classes of cases is that when diacetic acid is present dietetic restrictions must be made much more cautiously, a liberal supply of alkali being given at the same time. There is no doubt that many patients have passed into coma soon after they have been put upon a strict diabetic diet. If patients really adhered to the diet ordered this would have happened oftener. If any severe diabetic is given such a diet, within a few days he is liable to become drowsy and to suffer from distaste for food, pain in the abdomen, nausea, and constipation. These symptoms commonly pass off, but they may lead to coma. Beddard, Pembrey, and myself[2] have shown that this state is pathologically identical with the early state of coma, as it certainly is clinically, and is associated with a fall in the alkalinity of the blood and in the amount of carbon dioxide in the expired air. In severe cases, then, you must be careful before each

[1] Lecture I. was published in THE LANCET of Oct. 28th, 1911, p. 1184.
[2] See THE LANCET, May 16th, 1903, p. 1366. Brit. Med. Jour., vol. ii., 1910.

restriction of diet to see that the urine is made neutral by giving bicarbonate of soda.

You may say, with all these warnings, Is it essential to restrict the diet? The answer is that it is. Restriction of carbohydrate is, in the present state of our knowledge, the only means by which the power of the body to burn carbohydrate can be restored. It is astonishing what an improvement follows when you have successfully led your patient on to a strict diet; and, on the other hand, how easily the assimilative power is lost again, and all your work undone, if the patient succumbs to the temptation to indulge in an excess of starchy and sugary foods.

ARRANGEMENT OF DIET.

In the cases associated with diacetic acid in the urine, when you have reached the strictest diet which I have mentioned so far—namely, that described in my last lecture, containing 46 grammes of carbohydrate—you will not infrequently find that sugar is still present in the urine. In that case you must put your patient on a protein and fat diet containing only traces of carbohydrate, prescribing at the same time a suitable quantity of alkali. Here is such a scheme:—

Breakfast.—Bacon and eggs; starch-free bread, butter; sugar-free marmalade; coffee, with cream.
11 a.m.—Half-a-pint of sugar-free milk; diabetic biscuits, with butter.
Lunch.—Fish, or lobster; starchless bread, butter, and cheese; sugar-free ginger ale, lemonade, or lime juice, or whisky and water.
Tea.—Tea, with cream; two boiled eggs, with starch-free bread-and-butter; diabetic biscuits and cakes.
Dinner.—Clear soup, fish, meat, poultry or game; egg custard, made with cream and sweetened with glycerine; starch-free bread; cheese; beverages as at lunch.

On such a diet large quantities of meat and fat must be eaten if the needs of the body are to be met. With mixed food we usually derive half of the caloric energy we require from the burning of carbohydrate. All this must be made up with protein and fat. Ordinary helpings of meat and fish are insufficient. The patient should have two or three dishes of meat and fish at dinner, if possible, and eat freely of each.

After a day or two of the strict diet the sugar, if any, persisting in the urine is derived from the tissues and not from the food. The diet should be continued so long as the sugar in the urine is falling in quantity, provided that the general condition of the patient is good.

A further reduction in the sugar may be obtained in some cases if opium is given in doses of half a grain upwards three times a day, or codeine beginning with half a grain twice a day and increasing the dose until 4–6 grains a day are being taken; or, if neither of these leads to much improvement, in some cases aspirin in doses of 15–45 grains a day will lead to a fall of the amount of sugar in the urine. None of these drugs, however, have much effect if the diet is not being regulated.

Lastly, the effect of a day upon a diet consisting mainly of vegetables such as I will detail to you when speaking of the oatmeal "cure" may be effectual in further reducing the sugar.

In cases in which you cannot get rid of all the sugar in the urine attention is then directed to finding out on what diet most carbohydrate is utilised. In such it is of more importance for a good deal of the carbohydrate to be assimilated than it is to get rid of the sugar in the urine. Hence when you add carbohydrate to the diet you must observe carefully not only whether or not there is an increase in the amount of sugar in the urine, but how much that increase, if present, is in comparison with what was added to the food. For instance, if a patient on a strict diet is passing 40 grammes of sugar a day, and on adding 4 ounces of bread the amount rises to 60 grammes, then we know that of the 72 grammes of starch in the 4 ounces of bread 52 were assimilated and 20 added to the unoxidised sugar in the urine. The patient, therefore, has gained 52 grammes of carbohydrate, which will give him over 200 calories of energy and will save him from having to expend a corresponding quantity of fat or protein.

When you have made these observations upon various diets you will be in a position to make regulations which will vary according to the results you obtain and the circumstances of each patient. In some cases the diacetic acid and sugar will disappear and remain absent if the patient takes a diet with moderate restrictions, and will not reappear when most of the restrictions are gradually removed. In others more stringent injunctions must be given. The best way to maintain the assimilative power over long periods is to interpose a day or more of strict diet at fixed intervals. For example, a patient two years ago excreted 60 to 80 grammes of sugar a day and suffered from eczema and boils. The urine gave a strong diacetic acid reaction. Restriction of diet with alkalising of the urine led to very little reduction of the sugar. He was then ordered a varied diet containing about 50 grammes of carbohydrate, since the addition of this amount only led to an increase of 15 grammes in the urine; that is, $50 - 15 = 35$ grammes were utilised. But on one day in every week an absolutely strict diet was taken containing only the foods in List 1 and the various starchless foods sold. Under this treatment the sugar in the urine fell in a year to an average of 40 grammes, and the diacetic reaction was reduced in intensity. The carbohydrate was then reduced to 25 grammes a day with one absolutely strict day a week; nine months later the average excretion in the urine is 20 grammes, the patient being in good condition.

In other patients it is often a good thing to advise one strict day a week and three consecutive strict days a month—say, for example, the last three days of the month.

But some patients not only cannot tolerate great restriction, but do badly on it. In all difficulties the weight of the patient will be an important guide. Do not focus your attention too closely upon the amount of sugar passed out. The general nutrition and the risk of acid poisoning must in severe cases receive first attention. If the weight is falling after dietetic regulation has been tried you will often do wisely in increasing the carbohydrate, especially in the form of oatmeal, or, in some patients, of potatoes.

FULLER EXAMINATION OF THE URINE.

I have so far only spoken of investigations into the disordered metabolism of this disease which you can yourselves carry out. I must not conceal from you, however, that other information can be obtained from a fuller examination of the urine, which is of great value in the prognosis and in the treatment of the disease. The estimation of the ammonia gives information as to the severity of the acidosis and the effect which the administration of alkali has in neutralising the acids produced. The estimation of diacetic acid and acetone, which is carried out as one estimation after converting the diacetic acid to acetone, or of acetone separately, will show what effect the treatment has upon the production of those bodies. The estimation of the total nitrogenous metabolism will give information as to the diet which is most useful in helping you to maintain the nitrogenous balance. For these purposes repeated determinations must be made, and the work will involve the whole time of an analyst so long as the patient is under accurate observation. Such a method of dealing with a case ought to be carried out whenever possible, to the great advantage of the patient, but unfortunately the expense is considerable.

You will see, gentlemen, how individual a matter is the treatment of diabetes. There is no generally applicable rule. Both restrictions and allowances may do good and harm according to the state of metabolism of the particular patient.

BEVERAGES.

Tea and coffee, of course without sugar, water, aerated water, and the sugar-free lemonades, lime-juice, and other beverages now sold may be drunk. The fluids should not be restricted. The cause of the thirst is the accumulation of sugar in the tissues and blood, and abundance of fluid is required to enable the kidney to turn it out with a minimum of labour. As soon as the excess of sugar in the tissues is reduced by dietetic means the thirst is allayed. Opium also reduces thirst, but merely by lessening sensation, and cannot, therefore, be recommended for this purpose.

Diabetes is a disease in which you would expect alcohol to be of value, for alcohol is an oxidisable carbon compound which can to some extent replace carbohydrate or fat in the food. It has been very widely used in diabetes and a good number of observations made, from which it is clear that alcohol has little or no effect upon the quantity of sugar in the urine. The fact is, the amount of food value in the form of alcohol which can be got into the body without causing symptoms of poisoning in an ordinary individual is comparatively small. It has been observed, however, that less of the acetone bodies is passed out when alcohol is taken. The drug must, of course, be prescribed in a sugar-free form, such as that of well-diluted distilled spirit. Excess must be avoided, and has been known to precipitate a fatal ending.

DIABETIC FOODS.

The various diabetic breads and other foods sold are of the greatest value in the treatment of diabetes; indeed, it is only by their help that the proper conduct of many cases is possible. But you must have such foods examined from time to time, for many of them contain a great deal of starch. Some manufacturers are reliable, but you can seldom keep to one kind indefinitely because the patient will desire a change occasionally in order to obtain a variety of diet, and variety, as I have mentioned already, is necessary if the patient is to take a sufficient amount of food. You will recommend patients to keep to a few makers whose breads and biscuits have been found to be what they are represented, and whenever a new food is brought to your notice have it analysed. If your experience agrees with mine, you will also regard it with scepticism until the analysis has been made. The manufacture of starch-free foods, or nearly starch-free foods, is necessarily expensive, and such foods must sell at a high price. There is accordingly a large profit to be made by selling foods which contain a good proportion of starch as diabetic foods. You may regard any foods as satisfactory which contain under 5 per cent. of starch and sugar in the dried sample, as the specimens of Callard's and Protene bread, which Mr. Gardner has analysed for me, usually do.

There are some breads which do not profess to be starch-free, but which contain less starch than ordinary bread. These may be very useful to those cases whom you are allowing a measured quantity of bread, so long as you know exactly what you are prescribing. For instance, a patient who is allowed 3 ounces of ordinary bread in the day may take 6 ounces of Brusson Jeune bread, an increase for which he will often be very grateful. This bread would, however, be quite unsuitable for unlimited allowance among the foods of List 1.

Many patients will tell you that they have been taking brown bread or toast, or bread made from some flour which has a special reputation in the locality. Toast is, of course, equivalent to the quantity of bread used in making it. Nearly all the "special" flours of local fame which I have had analysed so far have contained nearly as much or as much starch as ordinary flour. Genuine diabetic bread is difficult to get in some parts of the continent. I have had several samples of gluten bread and almond bread sent for analysis from abroad which have contained 30 per cent. of starch.

THE "OATMEAL CURE."

I have mentioned that some patients bear one form of starch better than another. The "oatmeal cure" is founded on this fact. It must not be used in severe cases or in cases complicated by nephritis; and is only to be ordered after the course of dietetic treatment has led to a reduction of sugar in the urine to as low a figure as possible. Oatmeal porridge is taken in quantities of 8 to 10 ounces every two hours, while during the day 6 to 8 ounces of butter and 3 to 4 ounces of vegetable protein, or 5 to 8 eggs, are taken, cooked in various ways. Black coffee, tea, lemon-juice, and a little wine or diluted spirit are allowed. After three or four days a diet consisting mainly of vegetables is substituted for a couple of days; this diet includes tomatoes, cucumbers, asparagus, spinach, and cauliflower, with butter, bacon, and five or more eggs. After the two days 6 to 8 ounces of fish are allowed as well, then 6 ounces of meat, followed in a day or two by cheese and cream. The treatment reduces the diacetic acid and the acetone in the urine, and although so much starch is contained in the oatmeal the sugar also may be lessened.

British patients do not enjoy extraordinary changes in the diet so much as Continental ones appear to do, and I have usually applied this treatment in a modified form. The essential feature is to allow no other carbohydrate on the oatmeal days. The rotation of diets may be repeated, the patient returning to his former ordinary restricted diet when the "cure" is over. Diarrhœa may occur and should be controlled with laudanum—œdema is also reported.

EXERCISE AND OTHER MATTERS.

I have already referred to the well-known fact that the circumstances of the patient have a marked effect upon the progress of the disease. Always advise a patient to avoid over-work and, so far as possible, worry, and excessive fatigue, but do not advise him to give up his occupation unless it involves much travelling. Change of all kinds is bad for diabetics. Even the confinement to bed of severe cases when taken into hospital may bring on diabetic coma, as was first pointed out to me by the former sister of the William King ward. I have had the misfortune to see the observation verified since, so that I now never have patients who have been up and about before admission kept in bed the whole day. In private practice you will often find it wise to restrict the activities of the patient, but do not radically alter them. In milder cases the same directions apply, though with less force. Those who are able to choose where they live and what they do should be in the open air as much as possible and have some continuous, though not exacting, occupation or interest. Meals should be regular.

You must find out in the individual patient whether exercise does good or harm. In many cases moderate exercise, such as riding on horseback, cycling, rowing, or walking, is beneficial, improving the appetite and leading to a reduction in the excretion of sugar. In the patients of a severer type, on the other hand, much exertion may do harm. Over-exertion or exposure is harmful in all and may be dangerous.

DIABETIC COMA.

I must say a few words in the short time remaining about diabetic coma. The marked feature of diabetic coma—namely, air hunger—exists for some days before coma itself becomes developed. In all severe cases of diabetes not doing well you should, therefore, examine the exposed chest to see if the expansion is greater than normal. If it is, increase the dosage of bicarbonate of soda to 3 drachms every two hours and allow carbohydrate to be taken freely in some easily assimilable form, such as potato soup made with milk, or oatmeal gruel. You must not attempt to give ordinary "diabetic" or protein foods. The bowels must be well opened by enema, followed by castor oil or a mercury pill, and the patient kept warm. If coma supervenes inject three pints of a 2 per cent. solution of bicarbonate of soda into a vein. Although recovery is very rare, several cases have now been reported in which early recognition of the condition and immediate treatment have led to recovery from coma, and even to the restoration of the patient to his occupation. I have seen such myself. The matter of importance is to recognise the symptoms which precede coma. These are constipation, nausea, loss of appetite, pain in the abdomen, expansile breathing, and drowsiness. When you are not called to the patient until the coma is fully developed, you may usually restore consciousness for a time by the intravenous injection of three pints of bicarbonate of soda solution or of saline solution. I have known such a temporary return to consciousness to be of great value in enabling the patient to give directions as to his affairs.

COMPLICATIONS.

I cannot discuss to-day the treatment of the complications of diabetes. The commoner ones, such as boils, carbuncles, eczema, neuralgia, and sciatica, are usually relieved under dietetic treatment combined with such other measures as are suitable to the particular condition. Retinitis also may disappear when the patient is dieted. Constipation must always be corrected. If dry gangrene appears no operation should be done, but the parts should be protected from infection by suitable dressings. Moist gangrene calls for immediate operation, although the risks of anæsthesia are increased in diabetes. Albuminuria is apt to develop in diabetes, but need not call for special treatment unless actual nephritis, as shown by casts or œdema or a very high blood pressure, be present; in that case the diet must contain less protein and more carbohydrate, milk being given in preference to other protein foods.

In conclusion, gentlemen, it must be admitted that the proper treatment of diabetes will make great demands upon your time and patience. In well-marked cases in the young the task is too often a disappointing one, for the disease, though it may be held back by your efforts, progresses. On the other hand, in the majority of patients who pass out dextrose in the urine and who seek advice in good time, you may expect to be able to give such instructions as may in many cases entirely restore efficiency and in others so regulate the life of the patient that he may continue to enjoy both work and leisure in complete relief from the symptoms which led him to consult you, and with full maintenance of nutrition.

TWO CASES OF SARCOMA OF THE THYMUS.[1]

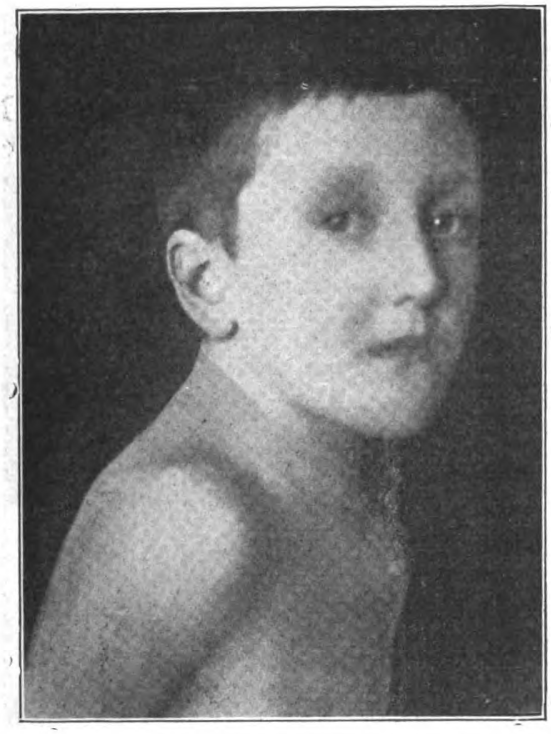
BY WILLIAM SHEEN, M.S. LOND., F.R.C.S. ENG.,
SURGEON, CARDIFF INFIRMARY; CONSULTING SURGEON, SEAMEN'S HOSPITAL, CARDIFF;

CORNELIUS A. GRIFFITHS, F.R.C.S. ENG.,
ASSISTANT SURGEON, CARDIFF INFIRMARY; CONSULTING SURGEON, PORTH COTTAGE HOSPITAL;

AND

H. A. SCHÖLBERG, M.B. LOND., D.P.H. CAMB.,
SENIOR PATHOLOGIST, CARDIFF INFIRMARY.

THESE are two cases of primary sarcoma of the thymus occurring in young males, in both of which the chief symptom that caused the patients to seek medical treatment was due to tracheal obstruction. In one, aged 7 years, relief was afforded by opening the superior mediastinum; in the second, aged 18 years, the conditions were more unfavourable, and the patient died soon after being seen.



CASE 1. (W. S.)—The patient, a male, aged 7 years, was seen at midnight on Feb. 12th, 1908, in consultation with Dr. T. Anstey-Chave of Cardiff because of threatening suffocation. Fulness of the neck had been noted for a month and dilatation of the veins of the chest for four days. The boy was much as usual, however, until Feb. 10th, when a slight degree of tracheal stridor was noted. This passed off, and on the 12th the child was playing about in comfort, and the parents did not recognise that the boy had any difficulty in breathing until just before midnight, when the symptoms were so urgent that they sent for Dr. Anstey-Chave.

On examination the boy had rapid breathing, stridor, and a constant short cough. There was a general fulness of the neck, most marked in the suprasternal notch; the veins of the neck and temples were enlarged and prominent, and the face was slightly livid. The upper part of the sternum was quite dull on percussion. There was a systolic aortic murmur. Discrete, slightly enlarged glands could be felt in the posterior triangles and in the groins. The spleen was slightly enlarged. The arms were not swollen and showed no enlarged veins. The lungs were normal. The boy breathed most easily in a nearly prone position with the left side lowermost, and in this position the cough was less. Pulse-rate, 100; temperature normal.

It was decided that the dyspnœa was due to intra-thoracic obstruction and that immediate interference was not necessary. The boy was moved into a nursing-home that night and kept under observation for some days, his condition showing little alteration. The severity of the dyspnœa varied, the boy sometimes breathing quite easily. On Feb. 22nd Dr. D. R. Paterson examined the trachea with Killian's tube under an anæsthetic (C.E. mixture), which was taken with little difficulty. The trachea was found compressed antero-posteriorly 7–8 rings down.

On March 1st an operation was performed, Dr. Anstey-Chave giving the anæsthetic and Dr. R. Walker assisting. An incision was made in the middle line from the cricoid to about half-way down the sternum. By dissecting between and dividing very large anastomosing superficial veins and by separating the muscles a hard growth was found projecting above the suprasternal notch; the supraclavicular glands on both sides were enlarged and hard. The manubrium was divided vertically in the middle line, separated transversely from the body of the sternum, and the two halves held apart by strong retractors. Further dissection exposed a hard, irregular tumour which extended beyond the area opened up. The whole process was most difficult and tedious because of the very large veins encountered and because the patient frequently stopped breathing and had to be turned over on to his face before respiration was re-established. The trachea was exposed and the pressure on it relieved by divaricating the lobular portions of the tumour, and removing fragments which lay immediately near the middle line and directly over the trachea. The vascularity of the growth was slight, and therefore allowed this process of *morcellement* to be carried out readily. The two halves of the manubrium were left separated, and the wound was closed with drainage. As a result of this operation the difficulty of breathing was at once and permanently removed.

FIG. 1.

CASE 1.—Reproduction of photograph of the patient.

For two days the patient was in a critical condition, suffering from constant vomiting and showing extreme cardiac weakness. He gradually improved and left the nursing home on March 25th; he then had a good appetite, but was getting thinner. Subsequently there was a progressive failure of health, with signs of secondary involvement of the lungs, liver, spleen, and glands. The difficulty of breathing never returned, the growth extending forwards between the separated halves of the manubrium sterni. The boy died on May 10th, and a necropsy was carried out on May 12th. The photograph shows the scar, and the growth projecting forward through the divided manubrium (Fig. 1).

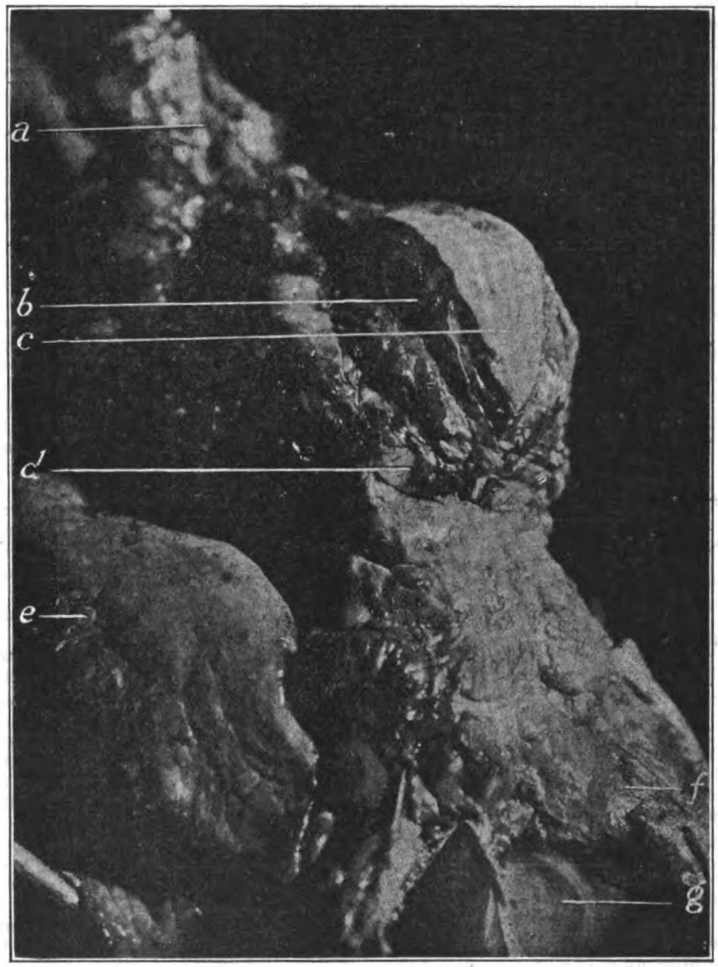
CASE 2 (C. A. G.).—The patient, a Swiss, aged 18 years, was admitted to the Cardiff Infirmary on Jan. 21st, 1910. Three weeks before admission he noticed a lump on the right side of the neck, which had since grown larger and had been associated with some difficulty in breathing. The dyspnœa was at first in attacks. The patient continued his occupation until three days before admission, when he was seized with a severe attack of dyspnœa while playing hockey. Since then the dyspnœa had been severe and almost continuous. On examination there were well-marked dyspnœa and orthopnœa; the patient breathed with his mouth wide open, and the accessory muscles of respiration were actively working. He was much cyanosed; the tongue and mouth were very dry. There was a diffuse swelling on the right side of the neck reaching from the suprasternal notch to the thyroid; it was hard, and did not pulsate or move on deglutition. There was dulness over and for about 2 centimetres on each side of the sternum, as far down as the fifth rib. The veins of the chest and upper part of the abdomen were enlarged.

Operation was carried out on admission. Under local anæsthesia a horizontal incision was made over the swelling, and the deep cervical fascia was incised. A large vein was cut and bled considerably. The skin incision was closed, and hot fomentations were applied. On the two following

[1] The first of these cases was communicated to the Cardiff Medical Society on Jan. 19th, 1909.

days the patient's breathing was easier and the cyanosis less. On Jan. 24th the patient was much worse and very cyanosed; he was sitting up in bed and breathing with the mouth wide open. The lower intercostal spaces were retracted. Tracheotomy was performed, and a small rubber tube passed with difficulty down the trachea to its bifurcation. A growth was noted spreading across the trachea. There was some relief, but the patient died half an hour later.

Pathological Report (H.A.S.).



Necropsy.

CASE 1.—A somewhat emaciated, well-developed male child. The operation wound was represented by a linear median vertical scar 7 cm. in length, situated over a hard oval-shaped tumour that hid the sternum from view. The mass projected 3·8 cm. beyond the surface of the bone, and had a maximum transverse diameter of 10 cm.

An exposure of the structures in the neck and thorax showed that the tumour presenting anteriorly infiltrated or enclosed the normal contents of the whole mediastinum, and extended up into the neck, invading the right lobe of the thyroid, and the sterno-mastoid and sterno-laryngeal muscles on both sides as well as the adjacent cervical glands. The main portion of the growth occupied the middle mediastinum and was pyriform in shape. It spread over and infiltrated the pericardium, the apex being attached to the upper surface of the diaphragm. Fig. 2 shows a side view of the growth in the neck and thorax.

Trachea and lungs.—The lumen of the trachea was narrowed along its whole course by the growth, which above lay over and below completely surrounded this structure. The cartilaginous rings just above the bifurcation were infiltrated by the sarcomatous tissue, the infiltration extending downwards along the trachea and bronchi into the substance of both lungs. Both lungs contained scattered nodules of growth. On the left side the obstruction of entry of air into the lower lobe of the lung was complete and had produced a pneumonic condition; only the upper lobe was left functional. On the right side, although the air entry was restricted, the lung was normal throughout except for the nodules of growth already mentioned. The glands at the bifurcation of the trachea were replaced by, and continuous with, the main mass of the tumour. The pleural surfaces of both lungs were studded with growths varying in size from a pea to a walnut.

FIG. 2.

CASE 1.—Reproduction of photograph showing (*a*) the growth on the right side of the neck; (*b*) the mass which has grown through the divided sternum; (*c*) the skin and scar; (*d*) a portion of the sternum; (*e*) a metastatic nodule on the surface of the lung; (*f*) the growth infiltrating the pericardium; (*g*) the heart. (Photograph by Dr. O. Ll. Rhys.)

Heart and great vessels.—The mass of growth lying over the pericardium and heart had a rounded apex like the ventricle. The infiltrated and much thickened pericardial sac contained a quantity of clear serous fluid, and the internal surface was of a dull white colour. The visceral pericardium showed two large plaques of growth which had penetrated the cardiac muscle: one situated at the apex of the right ventricle had a maximum diameter of 2 cm.; the other, 7·5 cm. long by 1–1·5 cm. broad, extended from near the apex to the base of the left ventricle. All the great vessels entering and leaving the heart were embedded in growth, but although the walls of the vessels were infiltrated their calibre was but slightly diminished.

Œsophagus.—This in the neck was normal, but in the thorax from just above the bifurcation of the trachea it was compressed and surrounded by growth down to the cardiac origin of the stomach. At this point the growth infiltrated the walls of the œsophagus, the diaphragm and the adjacent lung substance, fixing these structures firmly to each other.

Abdomen.—The metastases present included secondary nodules in the liver and kidneys, and in the lymphatic glands in the neighbourhood of the cœliac axis. The liver showed in addition a few small areas of congenital cyst formation (the spleen and kidneys, however, being normal in this respect). There was no ascites.

CASE 2.—Well-nourished, muscular subject. The structures of the neck and thorax were exposed in the usual way. The tracheotomy wound had divided the cricoid and the first two rings of the trachea. A massive nodular growth was found, which extended from the level of the lower border of the thyroid cartilage above into the thorax, filled the superior thoracic opening, and hid the great vessels and heart from view and pushed the lungs on one side.

Neck.—The growth, while occupying the anterior and posterior triangles on both sides of the neck, was larger and extended further upwards on the right than on the left side. The lower pole of the right lobe of the thyroid was infiltrated, and the great vessels of the neck on both sides were surrounded and infiltrated by growth. The sterno-mastoid and sterno-laryngeal muscles were firmly blended with the tumour.

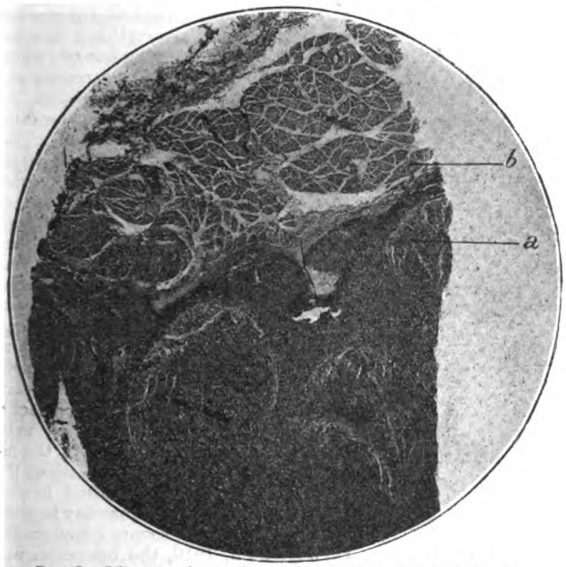
Trachea and lungs.—The trachea was compressed from before backwards along its whole course, the lumen of this tube and of the bronchi being narrowed right up to the entrance of the latter into the lungs. The walls of the trachea and bronchi were but slightly infiltrated, the growth chiefly enclosing these structures all the way from above where it hung over the tracheotomy wound down to the roots of the lungs. The glands at the bifurcation of the trachea were much enlarged and replaced by malignant growth. The lungs were normal and showed no metastatic nodules.

Heart and great vessels.—Lying over the pericardium was a smooth hard pyriform mass which had the appearance of a second superimposed heart. The apex of this portion of the tumour was free, while the base blended with the main mass, enclosing the great vessels. The external surface of the pericardium was infiltrated with growth, but in no place had it pierced the wall of the sac, the internal surface of which was smooth and glistening. There was no fluid in the pericardium. The heart showed no metastatic growths.

Abdomen.—This was normal. There was no ascites, nor were there any metastatic growths or naked-eye evidence of any congenital abnormality.

Anatomy of the Growths.

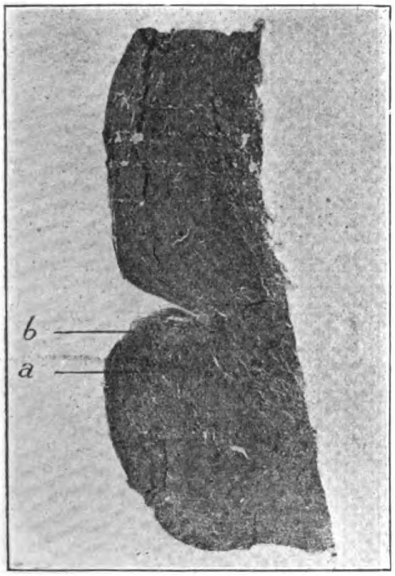
CASES 1 AND 2.—The *naked-eye* appearances of the main masses in the thorax and neck were identical; in both they occupied the same position and possessed in the chest the same lobate contour and hard smooth surface. A median section showed the same characters—namely, a firm, uniformly solid, avascular growth without any areas of softening or cyst formation. Both extended in a similar way up into the neck, following the line of the position of the thymus. The most striking difference between the two cases was that in one, the younger patient, the sarcomatous growth was disseminated, while in the older patient it remained localised.



The *microscopic* characters of the growths were identical in both, and without reference to the record on the slide it was not possible to distinguish one from the other. The tumours consisted of closely packed, small round cells with a deeply staining, relatively large rounded nucleus and a scanty protoplasmic content. The stroma was very poorly developed, and the blood-vessels were small and very sparsely distributed. The morbid anatomy and microscopic appearances were those of a small round-celled sarcoma. The micro-photographs show from Case 1 the metastatic nodule near the apex of the right ventricle of the heart (Fig. 3) and from Case 2 the infiltration of the vena azygos major by the growth (Fig 4).[2]

[2] For these micro-photographs we are indebted to Mr. E. Barton White, and for the facilities for producing them to Dr. E. Goodall, medical superintendent of the Cardiff City Mental Hospital.

Commentary.



Clinical.—These two cases are examples of a rare condition. In the first case the bilobate character of the growth as revealed at operation, coupled with microscopic examination of some of the pieces of growth then removed, allowed a probable diagnosis of sarcoma of the thymus to be made during life. Both cases were in young males and showed an acute onset; dyspnœa, at first in attacks; dilated veins of the neck and thorax, swelling of the lower part of the neck, and dulness over the manubrium. Direct laryngoscopic examination was of value in determining the site of the obstruction. Division of the manubrium sterni and the removal of portions of growth pressing on the trachea permanently relieved dyspnœa. The clinical conditions unfortunately seem to show that there is little hope of ever getting a case so early that the growth can be entirely removed.

FIG. 4.

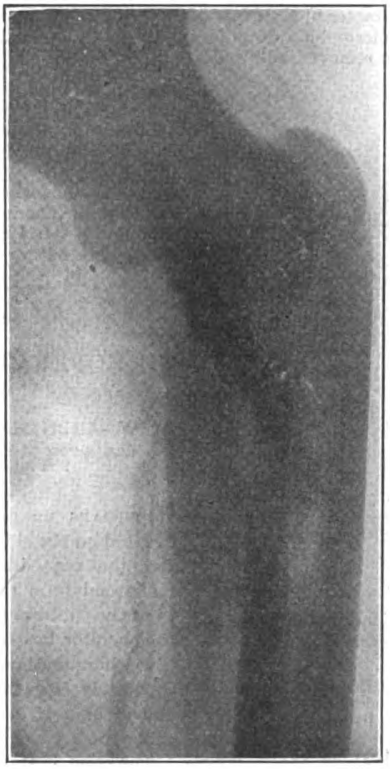
CASE 2.—Microscopic section of a portion of the vena azygos major. (*a*) Sarcomatous growth extending right up to (*b*) the endothelial lining. (Photograph by Mr. E. Barton White.)

Pathological.—That these two cases were sarcomata arising primarily in the thymus is suggested by the fact that the main mass of the growth in the chest occupied the situation and had the shape of the thymus. The character of the growth in the neck likewise supported this interpretation, for both cases showed an asymmetric distribution in which the chief bulk of the tumour was on the right side in the position occupied by the thymus when it is found in the cervical region. The microscopic characters, too, were consonant with a sarcoma arising in the lymphoid tissue of the thymus, and the malignant nature was established by the destructive infiltration of the surrounding structures and the distant metastases.

THE OPERATIVE TREATMENT OF BADLY UNITED FRACTURES.

BY W. ARBUTHNOT LANE, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

PERHAPS no operation in surgery may make a greater demand on the skill, resources, and ingenuity of the surgeon than that requisite to restore a badly united, useless bone to its normal form and functions. If an operation is resorted to at the time the injury is sustained the difficulties which the operator has to meet are relatively small, however great the comminution, since the fragments can be fitted accurately together and retained in position by plates and screws, if only the surgeon has enough patience and experience.



The chief obstacle that has to be overcome in many cases is the approximation of the edges of the skin incision and their retention in accurate apposition. This difficulty is experienced more commonly in fractures about or above the ankle-joint, but it may be met with in many fractures where there is much laceration of the soft parts, and especially when some time has been permitted to lapse since the receipt of the injury and the tissues have become inflamed. The earlier the operation is performed after the receipt of the injury the easier it is to carry it out effectually and rapidly. Michel's clips form the most effectual means I know for retaining the skin edges in accurate and efficient apposition. If accurate apposition is not established the wound may become fouled and the plates may come out. Such an accident means disaster to the patient. At the best it entails delayed union and probably some necrosis. In consequence of the softening of the bone in order to eliminate the screws, non-union of fragments is likely to occur. Again, such non-union is difficult to deal with by operative means, since the organisms which get into the wound lie quiescent for a very long time in and about the bone, and only become active when a plate and screws are introduced. The length of time these organisms will remain quiescent is remarkable and most disappointing to the surgeon who attempts to deal with a case that has once been fouled.

Surgeons are learning by painful experience that they cannot fix fragments in fractures by foreign bodies with the casual amount of asepsis they find sufficient for abdominal and other operations. Personally I believe that for some time the results that will be obtained by operation on simple fractures will at least be as hopelessly unsatisfactory as are those following non-operative treatment. Indeed, some surgeons seem to regard as normal the necessary removal of screws and plates by a process of suppuration, and are inclined to consider the infection as resulting from the presence of organisms in the blood rather than from their own insufficient precautions. This trouble will gradually be eliminated by increased experience.

I think it worth while to illustrate some of the difficulties one may meet by the consideration of two typical cases of badly united fractures. One represents a badly comminuted fracture of the femur which was operated on five months after the bone had been broken, and the other multiple

fractures of the tibia and fibula operated on 12 weeks after the injury. Both cases had been under the care of very eminent surgeons, and in neither, apart from operation, was there the slightest prospect of restoring the patient to active usefulness. Both cases are illustrated by radiograms taken at intervals. They are of particular interest since they show the manner in which callus serves to render secure the junction of a broken and deformed bone in which it has been impossible to obtain any large area of bone apposition without shortening the limb very materially and so reducing its usefulness and the symmetry of the individual in a corresponding degree. They also show that the crystallisation of lines of force, which I showed to be a striking feature in the fractures of young life, takes place progressively in a marked manner later in life and for a long period after the union of the fractured ends has been effected. This entails the careful retention of the leg for a considerable time in an apparatus by means of which the weight of the body is transmitted from the tuberosity of the ischium to the boot. Such an apparatus enables the patient to get about at an early stage of convalescence, while the gorging of the limb with blood consequent upon the dependent position of the leg during locomotion assists very materially in the formation of callus. Great care should be taken to encourage this engorgement within reasonable limits and to avoid any direct pressure on the seat of fracture which is likely to reduce its blood-supply. Such a splint was made for me in both these cases by Mr. C. A. Hoefftcke, and it served its purpose perfectly.

FIG. 1.

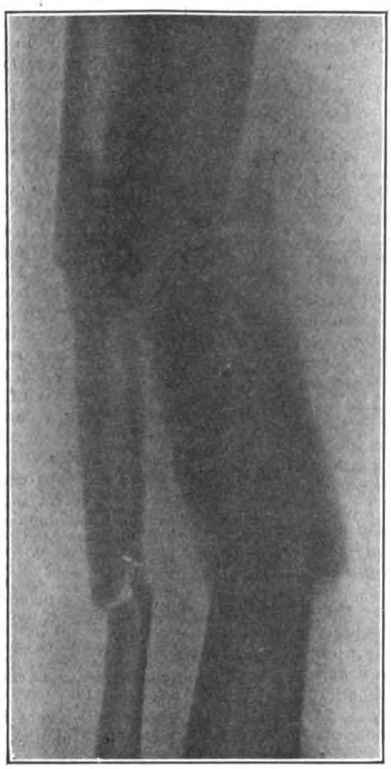
CASE 1.—Skiagram taken July 4th, 1910, showing condition of femur before operation.

The first case was that of a man, aged 46 years. On Feb. 1st, 1910, he fell in an aeroplane accident and sustained a very severe comminuted fracture of the upper part of the shaft of the right femur. Everything that was possible was done by means of splints, &c., but he was left with a useless and deformed limb. Fig. 1 shows the condition of the bone when he came under my care five months after the receipt of the injury. It is apparent from an examination of the radiogram that the junction was unsatisfactory in the extreme. The comminuted fragments were united by callus at a very bad angle, the union being scanty and imperfect. It also shows that, owing to the splitting of the shaft vertically and to the comminution of the fragments, in order to restore the limb to anything approaching its normal length only a portion of the segment of each bone could be employed to effect a junction, and that some delay must necessarily take place before the interval that would remain between the broken spikes could be filled in with new bone in sufficient quantity to make the femur perfectly secure functionally. On July 13th, 1910, the operation was performed. As was expected, it was only possible to utilise the blunt end and side of a spike of the lower fragment, which was placed in contact with a similar spike and blunt surface on the upper fragment. In this manner the length of the shaft was reduced

FIG. 2.

CASE 1.—Skiagram taken August 22nd, 1910, showing early results of operation

FIG. 3.



CASE 1.—Skiagram taken May 25th, 1911, showing firm bony union.

by only half an inch. A very stout steel plate, secured by means of eight No. 7 screws, three quarters of an inch in length and threaded up to the head, was placed in position so as to retain the fragments immoveably and firmly together. Fortunately the bone was very dense and strong. The patient made an uninterrupted recovery. On Sept. 13th Mr. Hoefftcke fitted him with his splint and the patient gradually got about with increasing comfort and facility. He was finally able to discard the splint after wearing it for some months. He now gets about easily and leads a very active life. Figs. 2 and 3 show the condition of the bone at intervals. Fig. 2 was taken in August, 1910, a little more than one month after the operation, and Fig. 3 in May, 1911, nine months later. They speak for themselves and hardly need any description. The amount of callus which was formed, and filled in the interval which existed between the fragments after the operation, has increased considerably and now exists in sufficient quantity to render the bone perfectly strong and efficient.

The second case was that of a powerfully built man, aged 56 years, under the care of Dr. Henry Menzies. He had sustained a severe comminuted fracture of the left tibia and fibula in December, 1910. The fractures were produced by direct injury, and there was much damage to the soft parts. The tibia and fibula were each broken in two parts, so that there were six separate large fragments of bone. Besides these there were several smaller pieces. The fragments had been so displaced that their several axes differed very greatly in direction and there was much overlapping, so that at none of the four fractures was there anything approaching apposition of the broken parts. The imperfect junctions between the tibial fragments were cleared, and their opposing surfaces were sawn so as to enable us to restore the bone to its original form; the cut surfaces were placed and secured in accurate apposition. To retain the fragments in position it was necessary to use six steel plates of varying sizes and strengths. No attempt was made to unite the fibular fragments. This would have increased the risks of the operation very much, while it would have afforded no sufficient compensation, as the fibular fragments would unite as soon as the tibia was functionally secure. As in the first case, the successful result was chiefly due to the skill and care of my assistants—most important factors in the performance of these operations. The patient made an uninterrupted recovery. Mr. Hoefftcke fitted a splint on May 8th, 1911, and the patient soon learnt to use it. Figs. 5 and 6 show the condition of the bone at intervals of five and seven months after the injury. The amount of new bone that continued to form even after the fragments of the tibia had apparently become firmly united was considerable. Fig. 6 showed that union is perfect between all the fragments of the tibia and fibula. The radiograms illustrated by Figs. 4 and 5 were taken by Mr. A. H. Greg, the others by Mr. W. A. Coldwell.

CASES ILLUSTRATING THE USE OF VENESECTION.[1]

BY R. FORTESCUE FOX, M.D. LOND.

IT would be difficult to find a parallel to the sudden revolution in treatment under which venesection disappeared from medical practice in the middle of last century.[2] Action and reaction are equal and opposite, even in the domain of opinion and custom, and no doubt it was inevitable that after ages of unquestioning and excessive depletion there should follow a period of scepticism and expectancy in treatment. But why did the tide go out so fast? At all events, in that ebb we trust there have been laid the foundations of scientific therapeutics. Specific methods, such as vaccine-therapy and organo-therapy, are being found for acute and specific diseases. The more complicated problems of chronic disease are being met by various forms of physical therapeutics, which bring the organism into effectual contact with the energies—whether thermal, electrical, chemical, radio-active or otherwise—by which we are surrounded.

Similarly I would venture to submit that increasing knowledge has shown us that there are both acute and chronic conditions of toxæmia, and disorders of the vascular system and of the distribution and pressure of the blood, in the treatment of which venesection has its proper and essential place. Both clinical experience and *a priori* reasoning have shown that no other treatment can here produce the same immediate and beneficial effects.

During the latter half of the last century there have been many authoritative voices to warn us that this potent method of treatment was too much neglected by the profession, and that lives could be saved by venesection that would otherwise be lost.[3] In this country Paget, Broadbent, Hughes Bennett, Heywood Smith, B. W. Richardson, H. G. Sutton, Hale White, Wilks, and Newton Pitt are among those who have advocated its employment. The test of practical experience has, moreover, not been wanting. Few years have passed in which there may not be found in the medical journals records of the use of venesection in various emergencies, and of the good results obtained even in apparently hopeless cases.

My own interest in the subject dates from the time when I had the privilege of serving as house physician to Sir Andrew Clark at the London Hospital. A series of cases then occurred in his wards in which a recourse to venesection brought astonishing relief in what seemed to be a desperate condition. It may be added that the house physician was himself glad to be relieved of the responsibility he had incurred in carrying out this measure when Clark, discussing the matter before the class, handsomely expressed his thanks to him for "reintroducing the practice of bleeding into these wards."

In the 27 years that have elapsed I have employed this treatment in a variety of conditions, often with immediate and striking benefit, sometimes with temporary improvement, and sometimes, I must confess, too late to be of any signal service. On no occasion have I found cause to regret the venesection, and never has any ill effect been noticed as a result of it. I have preserved records of 18 cases and 28 occasions in which I have had recourse to it.

In reviewing the whole it seems convenient to arrange the morbid conditions in which venesection is indicated as follows.

A. *Acute Cases.*

1. Some *acute pyrexial diseases* of a sthenic or fulminating character, with dangerous nervous or circulatory excitement. The severe pain of very acute pleurisy has been found by others as well as myself to subside immediately after a small venesection. The violence of the inflammation in sthenic pneumonia is also relieved by timely venesection.[4] It is indeed remarkable how rapidly the nervous and circulatory tension are relieved.

The so-called "physiological effects of venesection" give but a very imperfect idea of the effects produced by a small loss of blood in pyrexia and toxæmia.[5] According to A. Robin, it exerts an immediate action on nutrition and the organic exchanges; it increases pulmonary ventilation and oxidation, and is therefore indicated where nutrition is compromised by an insufficiency of oxygen.[6]

Recent observations also suggest that the natural power of resisting infective disease may be substantially increased by venesection. In certain circumstances bloodletting increases the production of antitoxins. Schröder of Copenhagen, by means of small bleedings of patients with enteric and paratyphoid fever, brought about a rapid increase of the agglutinative power of their serum. The immunity of animals to bacillus coli or bacillus typhosus may be in the same way restored or heightened. It is probable that the beneficial effects of venesection in acute disorders can be, therefore, to a great extent attributed to a similar augmentation of immunity.[7] From this point of view it is interesting to note that many cases of pulmonary tuberculosis in which hæmorrhages occur at an early stage very often run a favourable course.

2. *Toxæmias*, uræmic or otherwise, resulting in sudden attacks of dyspnœa, coma, or convulsions.

CASE 1.—A man, aged 50, with chronic Bright's disease and nearly blind from albuminuric retinitis, became suddenly comatose on April 1st, after headache and vomiting. Blood pressure was high, the left ventricle much hypertrophied. After bleeding to 6 oz. the attack rapidly passed. The second seizure on April 30th yielded promptly to venesection to 12 oz. He died from bronchitis on June 24th.

CASE 2.—A girl, aged 22, with cirrhosis and endocarditis. I was called to find her unconscious with epileptiform convulsions affecting the left hand, with deflection of the head and eyes to the left. The circulation was excited, the pulse 150, of a peculiar thrilling or purring character. Pulsation was also present in the veins on the dorsa of the hands, and the twitchings synchronised with the beat of the heart. I bled to 6 oz. with immediate relief.

Many observers have noted beneficial effects from venesection in uræmic seizures and puerperal eclampsia. "In no other way can one so quickly terminate the uræmic convulsions or cause the disappearance of uræmic coma."[8]

3. *Threatening asphyxia* and cyanosis, or dangerous circulatory embarrassment in heart disease, thoracic aneurysm, bronchitis, carbonic acid poisoning, &c. In this condition it would seem that not only does the blood accumulate in the veins, but that the arteries are contracted. The right side of the heart therefore acts at the greatest possible disadvantage. The opening of a vein in such circumstances naturally relieves cyanosis, and, judging by its effect upon the pulse, it appears in some reflex manner to relax the arteries and lower arterial pressure.

CASE 3. *Thoracic aneurysm.*[9]—A woman, aged 29, lay in the London Hospital in 1884. She was married, without children, one miscarriage, and had signs of a mediastinal tumour. For six months she had had cough, wasting, and attacks of dyspnœa. The case led to many diagnostic discussions. By most it was regarded as malignant, by myself as aneurysm. She continued for nearly one year, frequently seized by acute dyspnœa. At such times I frequently bled to 4 oz., 6 oz., or more, and have noted that on one occasion the pulse sank during the operation from 138 to 108 with immediate relief to the breathing. Post mortem a large aneurysm was found pressing on the trachea.

CASE 4. *Aneurysm of subclavian artery.*—The patient was also a woman, but in this case the dilatation was probably congenital. At 34 years of age, after mental and physical strain, the swelling became larger and rose into the neck with increased pulsation and distress. Mr. C. A. Ballance, who saw the case with me at this time, feared that a rupture might be imminent. The patient had been already confined to bed and icebags applied. She was now on two occasions bled to 10 oz., and expressed herself as delighted with the immediate relief. Nearly two years have elapsed, and there has been no return of the acute symptoms.

CASE 5. *Heart disease.*—A woman of great mental energy, but full-blooded, suffered after the change of life from gouty symptoms—"burning feet and hands," inactive skin, anginiform pains and winter bronchitis. At 60 the heart was found slightly dilated, the pulse 114, and dyspnœa occurred on the slightest exertion. With ordinary treatment and the use of Nauheim baths she managed to continue her active life, but at 64 matters became worse. There were noted now, frequent attacks of cardiac asthma on the slightest mental or physical fatigue, skin dry and burning, veins over-full, heart's dulness extending to the right edge of the sternum. She was accordingly bled to 14 oz., and

after the operation returned home in a cab rather faint. The relief to respiration was marked, and the attacks did not return for four months. A year later she died from general cardiac failure.

Such cases presenting painful circulatory embarrassment, which ordinary remedies have failed to relieve, cannot be uncommon. But in this, as in other instances, it was impossible not to regret that one did not resort to venesection sooner, so great was the benefit obtained from it, even at a late stage. A remarkable example of the restoration of the circulation by means of timely venesection in a case of gunshot wound of the chest with hæmothorax has been recorded by Captain F. J. W. Porter, R.A.M.C.[10]

4. *Cerebral hæmorrhage, actual or threatened.*—How many lives in the full exercise of mental if not physical power are terminated by this accident. How many brain-workers, physicians and statesmen, have died at a little over 60 years of age from the sudden paralysis induced by the pressure of blood upon the brain! In some families the fatal liability belongs almost to a particular year. We shall presently consider to what extent this liability may be overcome and accidents prevented. The following cases, like others that have been published,[11] show that life may be saved by venesection even when there is reason to believe that hæmorrhage has taken place. There is no condition in which venesection is more appropriate than an apoplectic seizure in cases of chronic arterial hyperpiesis. It is difficult for those who have not witnessed its effect to credit the rapid fall in blood pressure and the restoration of tranquillity to the circulation and nervous system that often ensue.

CASE 6.—A patient, nearly 70 years of age, stout and plethoric, suffering from indigestion, shortness of breath, and discomfort in her head, went to a certain sulphur spa and drank the waters without advice. The congestive symptoms were dangerously increased, and one afternoon, whilst sitting on the sofa, she suddenly lost her speech, became confused, dropped the book she was reading, fell back, and became unconscious. I saw her a few minutes later and found the unconsciousness deepening into profound coma. The face was purple, the pupils fixed and dilated, the limbs moved convulsively at intervals, and the right cheek flapped in respiration. I bled her immediately from the left arm. The force with which the stream came was extraordinary. Presently the convulsive movements ceased, and the pulse, which had been very excited, sank in frequency and force. Believing that no half measures could suffice to check the hæmorrhage probably taking place in the brain, I determined to go on almost as long as the blood would flow. In the end I took 35 oz. In eight hours she regained consciousness, and on recovery declared that she was better than she had been for years. Her right leg and arm were weak for some months afterwards and she was liable to confusion of speech and some want of memory for words when taxed with conversation. For several years afterwards, leading a guarded life, she remained quite well.

CASE 7.—With regard to this patient several members of her family on either side had died from apoplexy at from 60 to 65 years of age. Since the climacteric at 50 she had suffered from high tension and occasional tachycardia and gouty symptoms. At 54 she had hæmorrhage into the retina, and epistaxis occurred on several occasions during the following years. At 59 she was very unwell and restless; the blood pressure was found to be 190, the heart was dilated and hypertrophied with a ringing second sound, and the patient especially complained of liability to "congestion of the head" and pulsation. This condition was in a measure relieved by absolute rest, abstinence from meats, and the use of nitrites and calomel. The seizure occurred at 61 years of age. It came on with difficulty of speech, and consciousness was not entirely lost for two hours. I saw her 30 hours afterwards in consultation with Mr. E. A. Bullmore of Wisbech. She was profoundly unconscious, the heart labouring. After bleeding to 14 oz. the pulse fell from 114 to 90. The next day the patient recognised her children and raised her right arm, but died with œdema of the lungs three days after the onset.

In connexion with cerebral hæmorrhage it is interesting to recall that venesection has been successfully employed in cases of fractured base with hæmorrhage.[12]

B. *Certain Chronic Disorders with Habitual High Arterial Tension.*

Many of the emergencies for the relief of which venesection may be properly employed occur in persons who suffer from chronic arterial hypertension. It is now an easy matter by instruments of precision to measure and record variations of blood tension with far more exactitude than when the *tactus eruditus* of the physician was his sole guide. Increased tension constitutes one of the commonest of chronic disorders, even at a comparatively early age, and it is associated with many of the more serious maladies of middle and later life. It is unfortunately subject to progressive increase and to sudden and dangerous exacerbations. The most effectual treatment of hypertension must therefore be by way of prevention, and it is as a preventive treatment in many cases that periodical venesection plays an important part. We know that in nephritis a natural relief is frequently obtained by epistaxis, and in cirrhosis by hæmorrhage into the bowel. In a middle-aged man now under my observation a decided improvement in health has followed a smart hæmorrhage from the urethra. The same effect can be seen when the menses are re-established in cases of amenorrhœa. Even in young subjects with chronic ailments, and especially in nephritis, it is probable that, *a fortiori*, where hæmorrhages have occurred or retinal changes or circulatory embarrassment are present, an occasional small venesection would be helpful.

In middle life, especially at or after the climacteric epoch in women, there is often—particularly in persons of gouty family—a marked increase of blood pressure, with a variety of discomforts. Severe and intractable headaches, vertigo, vertical pressure, depression, restlessness and nervous prostration, flushing and burning heat, with præcordial pain and palpitation, swelling of the limbs, fulness of veins, stiffness and pains in the muscles or the joints, are among the symptoms that indicate a condition to which the word plethora used to be applied. Sometimes relief is obtained by profuse perspirations or catarrhs, diarrhœa, or epistaxis.

CASE 8.—A lady, aged 47, of gouty inheritance, who had had rheumatic fever at 29, suffered from a uterine polypus with frequent hæmorrhages. The heart presented a systolic murmur with a highly accentuated second sound. She complained of occasional giddiness and dyspnœa and anginiform pain during the cold winds of winter. At 49 the polypus was removed and the hæmorrhages ceased. There followed a sense of heat, flushing, præcordial pain, depression, restlessness, gouty swellings, and neuritis. Treatment at Aix-les-Bains relieved the high tension, as also in the following year prolonged baths at Loeche-les-Bains (130 hours in the baths). Two years later, in May of the present year, the congestive symptoms having returned, I bled to 12 ounces, with marked relief of all symptoms.

CASE 9.—A patient, stout, sanguine, and energetic, presented herself for spa treatment on account of tender feet and breathlessness on exertion. She came of a gouty family, the catamenia had ceased four years, and she had undergone much strain in nursing a relative. Some relief was obtained from baths. The following year there were attacks of vertigo, heat, and pain in the head, also occasional præcordial pain and accentuation, her condition suggesting the note "post-menopausal congestion, threatening apoplexy." For two years she continued under strict diet, the use of calomel and salines and thyroid extract. Later, subconjunctival hæmorrhages occurred, and the venous system being turgid and the symptoms again threatening, I bled to about 15 oz. The resulting relief was so marked that the patient herself requested a repetition of the same treatment at the hands of another medical man twice in the following year. Four years having elapsed, this lady writes that "the bleeding has done her a great deal of good," and that the vertigo has not returned.

CASE 10.—Three members of this patient's family had died from apoplexy, the father at 62. She had persistent high arterial tension under my own observation for ten years, with occasional præcordial pains and an aortic murmur; also frequent complaints of anxiety, tightness, and breathlessness, and sometimes vertigo and tinnitus. At 66 there was a return of anginiform attacks and increasing blood pressure, for which she resorted with benefit to Royat. The following year the pressure again rose to 155, and later to 170, with a distressing sense of fulness, pressure, and apprehension, "as if she were going to have a stroke." A venesection was done to 10 ounces with great relief. Within two days the pressure fell to 122, and six months later remained at 110 to 115, the general condition being in every way satisfactory.

CASE 11.—This is the case of a friend whom I have advised medically for more than twenty years. At the age of 48, she had every sign of general plethora with vertigo and slight articular symptoms. The latter were regarded as a serious arthritis, but afterwards cleared up. At 54, the catamenia ceased and slight attacks of angina occurred. The arteries were contracted and "hypertonic." At 57, a hæmorrhage from the rectum; at 58, a transient right hemiplegia and aphasia, and an increased liability to vertigo, faintness, and dyspnœa. The skin was dry, inactive, and chilly, but all these symptoms were mitigated in the warm climate of Egypt where she wintered. The next year the heart was more uneasy, markedly hypertrophied, the peripheral vessels everywhere contracted, the head hot and flushed, and the extremities habitually cold. The blood pressure was 160. The late Mr. Marcus Gunn reported that the retinal vessels were small and evidently sclerosed. It was obvious that the irregular distribution of the blood and the inequality of vaso-motor tone imposed increased labour upon the heart and threatened the integrity of the brain. I therefore determined on venesection, and this was repeated generally twice in the year for about six years from 10 to 20 oz., and on one occasion 24 oz. being taken. At the same time the diet was reduced and meats of all kinds avoided. Marked and immediate relief of the symptoms attended every venesection. There has been now up to the present time (age 69) no return of the paralytic symptoms, the health is fairly good, and the pressures range from 140 to 160.

In conclusion, it will be seen that this ancient method of treatment, which so suddenly disappeared from medical practice, has been again employed in a guarded manner and with good results in a variety of cases. The chief indication for venesection has been stated by Dr. R. J. Pye-Smith and others to be "cyanosis with distension of the right heart."[13]

To this is attributed its beneficial action in mitral disease and in some cases of bronchitis and pneumonia.

No mere mechanical relief to the heart can, however, explain the observed effects. We have seen that venesection in some cases appears to influence in a favourable manner the progress of specific diseases, both acute and chronic, probably by heightening the natural resistance of the tissues; that it helps to restore the balance of the circulation and the normal distribution of the blood by a dilator effect on the arterial system; that a small venesection may have a powerful and apparently disproportionate influence, not only in quieting the circulation, but the nerve centres also. This is witnessed in uræmic coma or convulsions and in the crises of pain and dyspnœa in aneurysm. We have noticed that excessive blood pressures have been more or less permanently reduced by venesections far too small to produce such effects in a direct manner. Such facts as these suggest that the respiratory and vaso-motor centres are concerned in these actions; and that there are, in truth, morbid states of the circulation and the nervous system, both acute and chronic, which are in some unknown manner peculiarly sensitive to a slight reduction in the amount of the circulating blood.

THE PREVENTION OF ANTHRAX INFECTION DUE TO IMPORTED HIDES AND SKINS.

(THE SEYMOUR-JONES FORMIC-MERCURY PROCESS.)

BY CONSTANT WELLS PONDER, M.D., D.P.H. CANTAB., M R C.S. ENG., L R.C.P. LOND.,

SECOND STUDENT, JOHN LUCAS WALKER TRUST; BACTERIOLOGIST AT THE LEATHERSELLERS' COMPANY'S TECHNICAL COLLEGE, BERMONDSEY.

WORKMEN who handle imported hides and skins run a certain risk of contracting the dangerous disease set up by the spores of B. anthracis. Though goods from certain countries, such as China and the Straits Settlements, have a bad reputation in this respect, from our knowledge of the conditions under which the disease has been contracted we can scarcely describe as absolutely free from blame those of any particular country. The number of cases reported is not large—roughly, one case occurs annually among every 1600 engaged in tanning, and about 1 in 7000 die from the disease every year, but its dramatic acuteness and high mortality give it an importance not indicated by the actual figures.

Many attempts have been made to find a method suitable for disinfecting hides, but none hitherto suggested has survived the criticism of bacteriological or technical experts; either the process has failed to destroy the spores, coated as they may be by protective albuminoid material, or, on the other hand, it is condemned for its injurious effect on the hide and skin substance.

In this paper I wish to bring before the notice of the profession a method for which it is claimed that effective disinfection is brought about at a reasonable cost without damage to the material. This method is due to the suggestions of Mr. Alfred Seymour-Jones of Wrexham, a practical tanner and leather trades chemist. Before discussing Mr. Seymour-Jones's method, however, it will be as well to consider briefly the manner in which hides and skins convey the infection, the state in which they are imported, and the general conditions under which workmen contract the disease, matters with which I have dealt more fully elsewhere.[1]

I think it extremely probable that in hides and skin, as Dr. Eurich[2] has so plainly demonstrated to be the case in imported wool, the spores occur in their most dangerous form in blood and blood-stained material which has dried on the surface of the fur and skin; it certainly is fair to assume as a hypothesis that spores protected in this way are as resistant to disinfection as any, and if we are able to deal with these effectually there is not much danger from others that are present on the skin under slightly different conditions. In the animal dying from anthrax there is every chance of the skin and fur becoming contaminated with blood-stained discharges, which after drying are liable later on to form an infective dust; there is much evidence to show that spores do not form in the substance of the skin.

When the skin is removed from the animal it may be treated for preservation in several ways; we may divide these roughly into two classes. 1. Methods in which the skin is dried in the air or sun, and in which certain earths or chemical materials may or may not be rubbed in to prevent putrefaction. (The chemical materials in use may be assumed to have no action on the spores of B. anthracis, as infection from skins so treated has often taken place.) These methods may be called "dry-curing." 2. Methods in which the skin is soaked or treated with common salt or a strong solution of brine, so that, owing to the hygroscopic nature of this substance, real drying does not take place. This method of cure is known as "wet-salting."

Now experience has shown that very few, if any, cases of anthrax have been traced to infection from "wet-salted" goods, and the reason for this may be fairly easily conjectured. In the first place, they are not dusty, and so the spores are not so likely to gain access to the most susceptible parts—the face and neck. (Contrary to the general belief, hides and skins are practically never carried on the shoulder.) Then, again, the spores under damp conditions may tend to develop into bacilli and perish, as has been suggested by Spear.[3] We must, however, bear in mind that "wet-salting" is not the usual method employed in places such as China, where anthrax-infected skins are likely to be more common from the fact that no control is exercised over infected stock, but in places like Australia and North and South America, where anthrax-infected skins are not so likely to be brought in for cure.

Why, it may be asked, has not "wet-salting" become the usual method of cure? The answer is because the process must be carried out immediately after flaying the animal and it is difficult and expensive to carry salt to the semi-civilised places from which many skins are brought down; the freight of "wet-salted" goods is rather higher as they naturally weigh more; and, finally, the primitive methods of the natives are not easily changed. As a counter-balancing advantage to the increased cost, however, is the fact that "wet-salted" goods are better preserved, their condition and value can be more correctly estimated, and they are easier and safer to handle in the early processes of tanning. As a fact, no improvement in this direction is indicated by import statistics, the relative proportions having remained fairly constant during the last decade.

TABLE I.

Year.	Imports in hundredweights.		Percentage imported as "wet-salted."
	"Dry."	"Wet-salted."	
1899	446,725	763,548	63
1909	463,993	737,602	60

From the examinations I have made of dust, dirt, and blood-stained material taken from dry hides, I have come to the conclusion that the proportion infected is larger than one would have expected. For example, 25 samples of dirt, &c., were taken from dry hides lying exposed for sale in the Bermondsey hide wharves; no discrimination was used beyond choosing dirty and low-quality hides. Agar plates were made from emulsions in which non-sporing organisms had been killed, and from the first 31 satisfactory plates—that is to say, those which were not overgrown or showed hardly any growth—two undoubted colonies of B. anthracis were obtained. The finding of these isolated spores suggests that they were carried in contaminated soil rather than that the skin was taken from the carcass of an animal that had died from anthrax. It is interesting to note that one also very frequently met with organisms that were only distinguished from B. anthracis after a careful examination of their cultural and pathogenic characters. From the above-mentioned 31 plates 16 distinct types of anthracoid organisms were so obtained; these were indistinguishable from B. anthracis in the primary cultures.

[3] J. Spear: Anthrax in London Hides and Skins. Report of the Medical Officer to the Local Government Board, 1882.

If any process of disinfection is to be completely effective it is obvious that it must be carried out at a stage before opportunities of infection arise. In connexion with hides and skins it is essential that the goods should be disinfected at a stage previous to their being unloaded from the vessels, for statistics show that workmen in dockyards and warehouses are even more frequently infected than are those who handle the skins after they reach the tanyard. Thus, of 113 cases of anthrax during the seven years 1903–09 that were considered to be due to handling hides or skins, 60, a proportion of 53 per cent. of the total, occurred among those working in dockyard or warehouse, while only 42, or 37 per cent., occurred among tannery workers; it would clearly be therefore only a half-measure to disinfect the goods in the tanyard.

Before export the goods are collected by shippers at the ports of shipment and are there roughly cleaned, sorted, and baled, so that if a simple process of disinfection could be devised, there should be no difficulty in carrying it out at this stage, and this being done, all the cases of anthrax in the country of import would be prevented. Many suppose that certain outbreaks amongst animals in this country are due to the food-stuffs becoming contaminated when carried in the holds of steamers, trucks, &c., which have previously carried dry hides; if disinfection were carried out before shipment, this possible source of infection would also no longer exist.

To summarise the requirements of an effective disinfecting process for hides and skins:—

1. It must be capable of destroying the spores of B. anthracis when present on hides and skins under any of the conditions in which they may be supposed to occur naturally—e.g., when protected by blood dried hard.
2. It must not injure the hides or skins or interfere in any way with the subsequent processes by which they are converted into leather.
3. It should be simple, so that it can be carried out at the ports where the skins are collected and shipped.
4. It must not add considerably to the cost of the raw material.
5. It should not involve the use of substances of a nature dangerous or poisonous to those who have to carry it out.

Mr. Seymour-Jones's "Formic-Mercury" Process for Disinfecting Hides and Skins.

The "Formic-Mercury" process consists in placing the dry hides for 24 hours in a "soak" which is made up to contain 1-2 per cent. of formic acid and 0·02 per cent. of perchloride of mercury and then "salting" them with sodium chloride. The action of the "soak" is to swell up the fibres of the hide by causing them to absorb water, the result being that the hide returns to a condition closely resembling that in which it was when taken from the animal's carcass. This swelling action also affects the dry albuminous matter which may be supposed to protect the spores, the perchloride of mercury therefore permeates the protecting material and its full action can be exerted. Moreover, as has long been known, the presence of the weak acid prevents the rapid deterioration of the germicide from the formation of insoluble albuminates. After the "soak," the "salting," by again abstracting water, converts the hides into a condition which differs very little from the "wet-salted" state of a hide which had been so treated immediately after flaying.

By this process, essentially simple, we have a combination of factors which would seem to act harmoniously towards accomplishing the desired disinfection. In the first place, a good deal of cleansing must take place; then the hides are converted into the "wet-salted" state, a measure in itself of extreme value; finally, the spore is attacked by the perchloride of mercury, the action of which is accentuated by the swelling and penetrating effect of the acid and by the fact that under these conditions its germicidal power is not minimised by the formation of insoluble albuminates.

Let us consider how this process meets each of the requirements which, as stated above, are demanded by an ideal disinfecting method.

1. *Efficiency.*—Having followed the development of this process since its inception, I have had the opportunity of testing many combinations of different acids with perchloride of mercury and other salts on anthrax-infected materials and have satisfied myself that the action of this combination on the spores of B. anthracis is very profound. It is unnecessary here to recapitulate these tests, and it is sufficient to say that they led to the adaptation of the strengths described below, and confirm the final results.

The method that I adopted is fully described in the report previously referred to; it was briefly as follows:—

Test preparations were made by cutting out pieces of dry hide to a given weight. In the centre of each piece a drop of blood freshly drawn was allowed to fall, and before it clotted a loopful of emulsified spores of B. anthracis, taken from a strain obtained from a cow dead from anthrax, was thoroughly incorporated. The preparation was then dried and kept some weeks until required. When disinfection was attempted the proportion of the fluid to the weight of the hide was always the same as it would be under practical conditions. After disinfection the clot could be easily removed with a scalpel from the hide and introduced under the skin of an animal. Introduction into a culture medium was not found to be a satisfactory indication of the vitality of the spores, even if the free perchloride of mercury were neutralised with ammonium sulphide. Control tests with untreated clots always caused the death of a guinea-pig in less than 48 hours.

The results of tests on animals, kindly conducted by Dr. Graham Smith at Cambridge, are given in the following table:—

TABLE II.—*The Disinfecting Action of a Solution containing Perchloride of Mercury and Formic Acid on Anthrax Spores protected by Dried Blood on a Hide.*

(Weight of pieces of hide, 2·5-3·0 grm.; fluid used in disinfecting each, 25 c.c.; temperature of room, 60° F.; time of treatment, 24 hours; soaked in brine, 24 hours.)

Series.	Experiment.	$HgCl_2$.	Formic acid.	Result.
1	Two guinea-pigs inoculated with clot from hide treated with brine only (control).	—	—	One died in 36 hours; the other in 48. In both the appearances were typical and anthrax was confirmed by microscopical and cultural tests.
1	Ten guinea-pigs inoculated with clots from ten hides treated by full process.	0·01%	1·0%	Nine survived. One died after three days; the appearances were typical and anthrax was confirmed by microscopical and cultural tests.
2	Two guinea-pigs inoculated with clots from hides treated with brine only (controls).	—	—	One died in 36 hours; the other in 48. Appearances typical and anthrax was confirmed by microscopical and cultural tests.
2	Ten guinea-pigs inoculated with clots taken from ten hides which had undergone full process.	0·02%	1·0%	Six survived with no ill-effects. Four died; one after 6½ days, one after 7½ days, and two after 9 days. Anthrax confirmed by tests in every case.
3	One guinea-pig inoculated with clot taken from a hide treated with brine only (control).	—	—	Died in 36 hours. Typical appearances of anthrax. The disease was confirmed by microscopical and cultural tests.
3	Nine guinea-pigs inoculated with clots taken from nine hides treated by the full disinfecting process.	0·1%	1·0%	All survived with no ill-effects.
3	Two guinea-pigs into *each* of which clots from *ten* hides which had gone through the full disinfecting process were inoculated.	0·1%	1·0%	Both survived with no ill-effects.

We see in these tests that using a 0·1 per cent. solution of $HgCl_2$ in what amounts to 29 tests on guinea-pigs the clots were disinfected in every case. When 0·02 per cent. $HgCl_2$ was used in ten tests six clots were disinfected, whilst in the other four the spores were so altered that the death of the guinea-pigs only took place after about a week or more. With 0·01 per cent. $HgCl_2$ in ten tests the clots were disinfected nine times, but in one the guinea-pig died after only three days.

It would therefore appear that to ensure perfect safety one should recommend that a strength of 0·1 per cent. $HgCl_2$ (1 in 1000) be used. I think, however, that this is unnecessarily strong, for it must be remembered that one cannot

decide what strength of a disinfectant is appropriate for practical purposes by an opinion based on laboratory tests alone. Other considerations, such as expense, must be carefully taken into account. I am personally of the opinion that the most suitable strength to use would be 0·02 per cent. $HgCl_2$ (1 in 5000); I base this opinion on the following points:—1. The tests are as stringent as I could devise; in actual practice many of the conditions would be more in favour of the disinfection than in my tests—e.g., the higher temperature of the water in places like India, China, and the Straits Settlements. 2. The other factors in the disinfection—namely, the cleansing and the conversion into the "wet-salted" state—I regard as more important even than the actual destruction of the spores by perchloride of mercury. 3. Though the spores treated with 0·02 per cent. $HgCl_2$ in a small proportion of cases were able to kill a guinea-pig after the delayed period of seven days it does not follow that they would even set up the disease in man, who, there is evidence to show, is much more resistant to anthrax than the guinea-pig.

Little need be said as to the way in which this process is calculated to meet the further requirements of an ideal disinfecting method.

Injury to hides and skins.—In the opinion of the leading leather trades chemists and practical tanners who have experimented with this process no damage whatever is done to the goods, but, on the contrary, they are better preserved, easier to evaluate, and less likely to give trouble at the early stages of tanning since they are better preserved against putrefaction. The damage which $HgCl_2$ by itself does to the skin is prevented, since the formation of insoluble albuminates is inhibited by the acid which is present.

Application.—The process is a simple one, and it is clear that it could be carried out by unskilled labour in the ports of shipment. The necessary materials for the "soak" could be sent out in a concentrated state.

Cost.—Mr. Seymour-Jones estimates that the total inclusive cost of the process per hide would not exceed 3·75*d.* even in remote ports. When it is remembered that the value of a raw hide is roughly £1, the extra cost of disinfection cannot be considered appreciable. The process is not patented.

Danger to workmen.—There would be no danger in using $HgCl_2$ in the required dilutions; the goods would need very little handling.

A practical method having been suggested, how can its application be ensured to those goods which constitute a potential danger to our workmen? The American Government has led the way by making it illegal to import hides and skins into their country unless accompanied by a Consular certificate stating that there is no anthrax among the cattle in the district from which they are exported or that the goods have been submitted to a disinfecting process. As regards the first requirement, it is ineffective because the skins come to the port from far inland, whilst the second is useless because no effective applicable disinfecting process is suggested.

Civilised Governments should forbid the importation of hides or skins unless either (1) they have been submitted to the ordinary "wet-salting" process immediately after flaying; or (2) if cured by drying they have been converted back to the "wet-salted" state by the "formic-mercury" process before leaving the country of export. If such regulations were adhered to I am convinced we should hear no more of anthrax amongst the dock labourers and warehousemen in Bermondsey and Liverpool, nor of those sporadic cases which are continually cropping up in the tanneries in different parts of the country.

Pathological Laboratories, Cambridge University.

SERVICE FOR MEDICAL WORKERS IN BRIGHTON.—The annual special service for medical practitioners, nurses, and others engaged in medical work was held in Brighton parish church on Sunday evening, Oct. 22nd. The Rev. Dr. Upcott, head-master of Christ's Hospital, was the special preacher. In the course of his sermon he declared that the occupations which those in his congregation so well represented that evening were the purest and noblest in mankind if used in the right way and spirit, for it was pre-eminently a life of service. The collection was in aid of the Queen's Nurses' Fund.

THE TREATMENT OF BUBONIC PLAGUE BY THE IMMEDIATE INCISION OF THE GLANDS.

BY V. B. NESFIELD, F.R.C.S. ENG.,
CAPTAIN, I.M.S.; DEPUTY SANITARY COMMISSIONER, FIRST CIRCLE UNITED PROVINCES OF AGRA AND OUDH.

WHEN plague first appeared in Bombay in 1896, owing to mistakes in diagnosis, plague glands were occasionally removed. The patients were found to improve greatly for a few days, but ultimately invariably died from plague septicæmia. For this reason the removal of plague glands has been strongly condemned.

In 1905 I published the case (*Indian Medical Gazette*) of a Sowar of the 6th Bengal Cavalry who developed plague in Benares. On arrival in camp he fell off his horse and was found to have a large painful gland in the left groin. His temperature was 103·4° F. and his pulse was fast, weak, and dicrotic. He had severe headache and some delirium. The bubo had not been noticed six hours previously. An incision was made into the gland, which cut like a raw potato, and serum and blood escaped which showed swarms of the typical bipolar-staining bacilli. Iodine lotion (1 drachm of tinct. iodi to 2 ounces of water) was put into the wound, and a dressing soaked in this lotion applied. Two hours later the headache had disappeared, the temperature was 99°, and the patient was much better. Two days later the temperature rose again, but fell on opening the lips of the wound with a director. The patient recovered, and was able to continue his journey in three weeks' time. The case was a most severe example of bubonic plague. The gland was incised with the object of setting free the enclosed toxins.

During the severe plague epidemic in Lucknow in 1907 I treated 87 cases of plague in the cantonment. Sixty-two of these cases were bubonic and 25 pneumonic, septicæmic, and what might be termed splenic. All the bubonic cases (Lucknow cantonment) were treated by the immediate incision of the swollen glands. By this method the great majority of the truly bubonic cases seen within 48 hours of the appearance of the buboes recovered. But it should be noted that some people dead of the disease were seen for the first time in their houses, having died overnight, so that those brought in alive to hospital with buboes may be looked upon as showing some resistance to the disease. Of the 62 cases treated in this way eight died and 54 recovered, giving a mortality of only 15·3 per cent. A few of these were old-standing cases, and would probably have recovered without treatment, but some were hopeless on admission, and some were picked up miles away from their homes, having wandered during the night; these wandering cases generally died, so that a mortality of only 15·3 per cent. is remarkably good, and I believe better than any recorded. Surgeon-Captain Thomson gave a mortality of 62·7 for cases with buboes, and 78·6 for cases without palpable buboes in the Parel hospital in 1896–97.

There was every opportunity for studying these cases very thoroughly, as many of them were private servants, and notice was frequently given on the first sign of fever, and thus it was possible to see them from the beginning. The special feature of the bubonic cases was a one, two, or three days' fever, with rambling speech at night, restlessness, headache, backache, and vomiting, together with a normal or subnormal pulse tension. During this stage these cases resembled ordinary Indian fever, which one usually calls malaria, but with the difference that in malaria the pulse tension is high during the fever and there is no marked restlessness, headache, or rambling speech and there is sweating on remission.

After a day or so of this preliminary fever a large painful gland suddenly appeared in the groin, axilla, neck, behind the internal malleolus, the popliteal space, or behind the internal condyle of the humerus. The condition of the patient now became acute, the delirium very marked, headache very severe and the pulse very fast and dicrotic. Without treatment death usually results in these cases in from 3 to 48 hours.

Professor R. T. Hewlett in his "Manual of Bacteriology" states that 70 per cent. or more of the bubonic cases begin with the two or three days' initial fever.

Assistant Surgeon Thos. Whyte, of the Bombay medical staff, describing a case of plague in Káthiáwar in 1820, says: "She was in the ninth day of the disease, and had a bubo in the upper part of each thigh, both very painful to the touch, which came on the second or third day of a fever, which had deprived her for a time of her senses."

In General Gatacre's report of the epidemic in Bombay in 1896 the following sentences appear: "The glandular or bubonic is the common form of plague, and comprises 80–90% of all cases. ..... The swellings *sometimes* appear at the onset, *usually* on the second or third day, and often not until later in the course of the attack. They consist of single glands, or two or more separate glands agglomerated into a mass. ..... A sudden rise of temperature in the course of an attack generally indicates a fresh bubo."

Septicæmic type.—Enlarged glands may appear in several regions later on.

Pneumonic or thoracic type.—This type is very fatal, and in some cases is occasionally complicated with the development of external buboes, which arise from a secondary extension of the virus.

Dr. J. F. Payne in Clifford Allbutt and Rolleston's "Tropical Diseases" says: "Buboes are in some instances the first symptoms to attract the attention of the patient, perhaps by a sudden lancinating pain. More usually they occur after the onset of fever, on the second, third, fourth, or even the fifth day of the disease."

Special attention in this article is called to the preliminary fever as bearing on the true pathology of the disease and justifying incision. One is inclined to look upon the bubo as the initial lesion, and very naturally so, as a little fever is such a common event as to be overlooked by the native patient; moreover, one generally sees him for the first time with a swelling of a few hours' duration, frequently rambling in his speech and nearly moribund. The common conception of the pathology is that the bacilli enter by a skin lesion, travel up the lymphatics, and are arrested by the related superficial lymphatic glands. This is supposed to contra-indicate incision. It may be that a few bacilli lodge in the gland related to the inoculated area, though why they should, when the lymph channels are large enough for the passage of leucocytes, requires explanation. None of my cases had any local lesion; the Indian Plague Commission has altogether only reported four, so that the bacilli on first entering cannot be irritating. It is far more probable that they do not lodge locally, but enter the general circulation as rapidly as morphia when injected hypodermically. In some cases with a local cutaneous lesion the related gland is normal and a non-related gland is enlarged.

Plague should not be compared with an ordinary septic process, with a local cutaneous or subcutaneous inflammation and swelling of the related glands. It compares more closely with typhoid fever or acute osteomyelitis.

* Staff-Surgeon Wilm (Hong-Kong epidemic 1896–97) expressed the opinion, that infection through the skin is not common, "*for, on the one hand, in the great majority of cases, buboes do not appear until after the onset of the severe symptoms, and, on the other hand, were such a mode of infection common, we should expect to see much more frequently local affections of the skin.*"

I think that infection through the skin is the general rule, but the bacilli pass rapidly into the lymphatic and general circulation. The flea, prior to sucking blood, injects saliva to act as an anti-coagulant; the bacilli, which must be few at the most, are injected with the saliva, possibly directly into a capillary lymphatic or blood-vessel. The anti-coagulant, possibly by paralysing the local cutaneous and endothelial cells, may assist the bacilli. During the incubation period of two to ten days the bacilli probably develop in the spleen or elsewhere, and are probably responsible for the prodromal symptoms of lethargy and headache. They probably enter the general circulation again during the initial fever, as occurs during the first two weeks of typhoid. But immune bodies being also present the bacilli soon succumb, the few survivors settle down in a superficial lymphatic gland, just as typhoid bacilli settle down in the lymphoid tissue of the small intestine, and staphylococci in the epiphysial line of a growing bone in acute osteomyelitis. The election for the superficial glands is probably due to the fact that they are frequently the seat of small inflammations.

In No. 10 district, Bombay 1896–97, 85 per cent. of the plague cases were bubonic, and of these in 60 per cent. the femoral and inguinal glands were enlarged, in 17 per cent. the axillary and inguinal glands were enlarged, and in 9 per cent. the cervical and inguinal glands were enlarged. This is about the order and proportions in which these glands suffer from small inflammatory conditions. The organisms in the glands being shut off from the blood-stream, as in acute osteomyelitis, develop rapidly, and elaborate toxins, which in the case of plague may produce death in a few hours. Septicæmia tends to ensue as the disease progresses and the resistance of the body is broken down. In all cases of plague examined after death bacilli were found in the spleen. An acute attack of osteomyelitis can be cut short and the bone saved by early excision of the periosteum and opening the medullary cavity. Septicæmia is not produced by this interference; why, then, should one be afraid of septicæmia when opening a plague gland in the earliest stages?

Mr. James Cantlie, on p. 28, vol. ii., "The Plague in India," Government of India Home Department, says, "Plague is a polyglandular disease of an extensive nature." This is certainly not the case clinically in India. Nor have I seen swelling of the internal glands or mesenteric. The teaching that the disease is an extensive polyglandular one tends to make the physician feel that all attempts at treatment are futile; it is an untrue and over-melancholy aspect; as shown above, a very great deal can be done towards curing plague. Inoculation experiments on guinea-pigs (preparations in the College of Surgeons Museum) generally show post mortem an enlargement of the axillary and inguinal glands alone and great enlargement of the spleen. Post-mortem examinations of rats also demonstrate this point.

In addition to the bubonic cases there were 8 pneumonic cases with 6 deaths, 10 septicæmic cases with 6 deaths, 4 splenic cases with 3 deaths, and 3 mixed cases with 3 deaths. The total mortality of the 87 cases was thus 29·87 per cent. The mortality in the city of Lucknow during the same period was between 80–90 per cent., as it was a particularly severe epidemic.[1]

In nearly every case when a gland was incised the fluid was examined under a microscope; bipolar-staining bacilli were always present. The most favourable cases were those in which the gland swelling developed suddenly, and in which the gland tumour was large. In many cases after incision of one gland others developed in various parts of the body, sometimes in three or four places. In each case the swollen glands were incised as soon as they appeared. These secondary glands remote from the supposed original lesion prove that bacteria were present in the circulating blood. In some of these cases of multiple buboes B. pestis was found in a drop of blood from the finger. Most of these multiple cases recovered.

The pneumonic cases were mostly of a broncho-pneumonic type, the dull patches coming and going from day to day. The special features of these cases were blood-stained sputum (full of B. pestis) and great mental distress and horror. They were treated by frequent dry-cupping over the dull areas, absolute rest, and iron and digitalis internally.

The septicæmic cases always developed, sometimes only an hour before death, an œdematous swelling over some superficial gland. Other cases of a more chronic type developed true but smaller buboes than the strictly bubonic cases. These buboes as soon as they appeared were incised. The septicæmic cases appeared to be due to a primary or, at least, marked focus in the spleen, and perhaps these cases should more accurately be termed splenic plague. It is doubtful whether the B. pestis can flourish in the blood-stream without support from a localised lesion elaborating toxins; and there is reason to think that this focus is in the spleen.

There were 4 cases with special pain over the spleen, which I think were due to the spleen being involved in place of the superficial glands.

Every patient received the following mixture four times a day: Tinct. ferri perchlor., ♏xxx.; tinct. digitalis, ♏y.; glycerine, ℥i.; aq. ad ℥ii. The iron was given because it is so useful in diphtheria; the toxæmia of plague is not unlike that of diphtheria. In addition the patients were given 6 oz. of rum during the 24 hours and were fed hourly through the day with condensed milk and Horlick's malted milk. As much water and lime-juice as desired were given. The patients were kept absolutely at rest.

The management of plague cases is a difficult matter on account of the marked restlessness and in some cases actual mania. One boy of 18 wandered away at night, and was found in the morning under a tree more than a mile away. Three cases developed paralysis of the pharynx, and had to be fed with an œsophageal tube; many required catheterisation, while six had severe diarrhœa, with blood. Two cases

[1] It is very difficult to obtain the true plague mortality of a district, as the returns are compiled from police information. This year the mortality shown in some districts of the United Provinces was 100 per cent., in others 90 per cent.

never recovered their mental balance, and left the hospital insane. Morphia is the best remedy for the mania of the acute stage.

The Method of Making the Incision and the Dressing.

The skin was cocainised by intradermic injections of ½ per cent. cocaine and adrenalin; it was then freely incised, and the swollen gland or glands laid well open by two incisions crossing each other at right angles. The gland and subcutaneous tissues were not disturbed except for the clean-cut incisions. The wounds were dressed with absorbent wool, wrung out of iodine lotion (℥ 1 ad ℥ ii. water). The wool was then covered with oil paper and a layer of perchloride wool and bandaged. The wounds were dressed once or twice a day, depending upon the exudation.

The experience obtained from these cases shows that early incision into a plague gland produces an immediate improvement in the patient's condition. The temperature is lowered and the severe headache alleviated, and if the patient is seen during the first 24 hours the probability of his recovery is very great.

The theoretical reasons for immediate incision of the glands are as follows:—1. Toxins and bacilli are set free and exude into the dressings in place of the blood stream or lymphatics. 2. The incision relieves the intracapsular pressure (which is very great), re-establishes the glandular circulation, and thus the germicidal substances of the plasma are brought into the stronghold of the bacilli. 3. The incision produces a copious flow of serum containing alexin and plague antibodies. As is well known, alexin (complement) is a powerful germicide for cholera, typhoid fever, and plague bacilli that have been prepared by their specific antibodies. Bordet and Gengou demonstrated these antibodies in 1901, and their antimicrobic nature was demonstrated by Yersin. 4. Bordet, Gengou, and Levaditi clearly demonstrated that there was no alexin in circulating plasma; I was able to demonstrate this point also by mixing blood with 9 volumes of 1·5 per cent. salt and centrifuging immediately. The supernatant plasma contained no alexin, and did not clot on diluting with an equal part of water; hence the great value of serum over circulating plasma. 5. Never once were bacteria found inside leucocytes in smears taken from the glands. But leucocytes will readily take up B. pestis in the presence of serum from a plague patient. One must conclude from this that there are no opsonins (alexin?) in the intact gland, though these are present in the serum exudate of the divided gland. Hence division of the gland not only liberates toxins and bacteria, but also produces a flow of serum, lymph, and leucocytes containing immune bodies, alexin, and opsonins; so that the bacilli are not only destroyed directly, but are also engulfed by phagocytes.

The theoretical objection to incision is that the gland forms a barrier between the bacilli and the general circulation, any disturbance to this barrier being therefore fraught with great danger. As shown above, the plague bacilli reach the gland from the blood, and not *vice versâ*. It is probable that many reading this article will not be convinced of the very great benefit derived by immediate incision, but no one should be afraid of the experiment, for whatever other measure is undertaken eight to nine patients will die out of ten, while by employing incision only one or two will die out of ten.

In the Government of India's treatise on Plague, 1896–97, vol. ii., p. 28, Mr. James Cantlie states the following, which I wish to refute:—

> The result of experience gained by local, radical, or tentative treatment of the glands does not lead one to expect much benefit from them. That abscesses should be opened when they point, or when fluctuation is perceptible, is of course natural; but that local remedial steps should be undertaken for the purpose of affecting the course of the disease by acting on the gland is, from what we know of the pathology of the disease, scarcely rational. Injection of a swollen gland when it is accessible, as in the groin, with such substances as carbolic, perchloride of mercury, or a solution of the perchloride of mercury and iodide of potassium, has perhaps a theoretical basis of justification, but practically little good can be ascribed to it. The latter-mentioned solution may have a higher claim, as in several cases in which it has been administered, the temperature falls and the patient seems easier. *It may be, however, that the mere pricking of the tense capsule of the gland* even by needle punctures may serve to relieve tension and thereby pain. This leads one to the belief that subcutaneous incision of the gland may be attended with beneficial results, and it is a method of surgical procedure not without precedent. *Early free incision of the gland is not to be recommended*, nor can excision in any way be justified. The disease is a p lyadenitis of so extensive a nature, that eradication of infected glands is an impossibility. A gland, when swollen, red, and painful, may be smeared with glycerine and belladonna, or poulticed to relieve pain, and when fluctuation is perceptible it should be opened, but further procedure is useless.

Mr. Cantlie suggests that pricking or subcutaneous incision does good, but he prohibits a free incision. It would be interesting to know what experimental proof he had for the latter statement.

Identification of Plague in a Corpse.

Take a darning-needle, and drive the point into a penholder. Make a small cut in the skin over the spleen, and drive the darning-needle (eye forwards) into the spleen. On removing it, the eye will be found to be filled with spleen pulp. Smear this on a slide and stain with 1 per cent. watery methylene blue. Typical plague bacilli will always be found in a case of plague.

Protection against Infection.

None of the attendants or myself contracted plague, in spite of very intimate contact. The following precautions were taken: 1. Before examination the patient was brought out of his house into the open. In the plague hospital grass huts holding two patients only, and open at two ends, were employed. 2. Camphor was carried in the pocket, and the native attendants in addition were made to smear eucalyptus oil 1 part, sweet oil 60 parts on their calves, and all over their bodies once a day. No one was inoculated because in 1906–07 the vaccine was under preparation.

ACETONURIA IN CHILDHOOD:

A STUDY OF ITS PREVALENCY IN THE MEDICAL WARDS OF A CHILDREN'S HOSPITAL; WITH AN INQUIRY INTO ITS CAUSE.

BY ROBERT S. FREW, M.D. EDIN., M.R.C.P.,
MEDICAL REGISTRAR, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

THE acetone bodies, consisting of B. oxybutyric acid, aceto-acetic acid, and acetone, have long been recognised as occasional constituents of the urine in children, and their occurrence has been associated with more or less well-defined clinical groups. These groups may be classified as follows: 1. In diseases in which gastro-intestinal symptoms (diarrhœa, vomiting, or constipation) are prominent—e.g., in pneumonia, tuberculous meningitis, infantile diarrhœa, &c. 2. In cases of so-called "cyclical vomiting" where recurrent attacks of vomiting occur, associated with diarrhœa or constipation, and the presence of acetonuria. 3. In conditions in which fever is present. 4. Lastly, there is the toxic group, including diabetic coma, post-anæsthetic poisoning, and salicylic acid poisoning.

The discovery of acetone in the urine of children suffering from diseases not included in such a classification led me to make a more extended investigation into this subject, and the results are herewith set forth.

For the past year or so the urine of all children admitted to the medical wards of the Hospital for Sick Children, Great Ormond-street, where specimens were obtainable, has been tested for acetone. The cases were in no way selected, and so comprise instances of most of the diseases met with in children varying in age from a few days to 12 years old. In all, the urine of 662 children was so examined.

Method Employed.

At first only the specimen passed within 12 hours of admission was examined; in the latter cases, in addition, specimens passed about 36 and 60 hours after admission were also tested. Rothera's test for acetone, slightly modified by Dr. A. E. Garrod, was used in every case.

Rothera's test.—5 c.c. of urine are saturated with ammonium sulphate crystals, 2 c.c. of ammonia are added, and then a few drops of a freshly prepared 5 per cent. solution of sodium nitroprusside. Acetone gives a slowly developing permanganate colour. Dr. Garrod's modification consisted in adding to the urine an equal quantity of a saturated solution of ammonium sulphate in place of saturating the urine with $(NH_4)_2 SO_4$ crystals, thus enabling the test to be performed more quickly, without affecting its accuracy, as proved by numerous controls.

In the urine of children who have had rhubarb or senna a pink colour develops on the addition of the ammonia, due to

the presence of chrysophanic acid, but this is readily distinguished. The rapidity of the development of the permanganate colour gives a rough estimate of the quantity of acetone present.

In specimens obtained just after admission acetone was rarely found; those passed 12 hours after admission frequently gave a positive reaction. The maximum was found in the 36-hour specimens, and after that a gradual diminution occurred, all trace being gone by the fourth day usually. In cases in which the acetone was never very marked, it was in the specimen passed 36 hours after admission that it was most marked, sometimes being found in this specimen only. In those cases in which the acetone reaction was markedly positive the presence of aceto-acetic acid was also found by the use of the ferric chloride test.

Using the above method, the urine of 662 cases was examined, and in 408 of those, that is in 61·6 per cent., acetone was found. One is therefore justified in saying that acetonuria is of common occurrence in hospital children.

When an attempt was made to allot those cases to the groups mentioned at the beginning of this paper the result was unsatisfactory. There were two cases of diabetic coma, none of post-anæsthetic poisoning, none of "cyclic vomiting," 150, or 22·5 per cent., associated with definite gastro-intestinal symptoms, leaving 38·5 per cent. unaccounted for under such headings.

How, then, is the fact to be accounted for that 61·6 per cent. of all the children admitted to hospital develop acetonuria? In the first place the appearance of acetone in the urine is caused by abnormal fat katabolism depending on "carbohydrate starvation." This "carbohydrate starvation" may result from (1) deficiency or absence of carbohydrates in the diet, (2) a diminished power of absorption or assimilation of the carbohydrates, or (3) inability to digest the carbohydrates. It is therefore necessary to determine under which subdivision the "carbohydrate starvation" occurring in children on admission to hospital should be placed.

1. *Deficiency or Absence of Carbohydrates in the Diet.*

This is a well-known cause of acetonuria, examples of which are seen in the following two cases:—

CASE 1.—A male, aged 5½ years, a case of recovered empyema. The patient, who had been eight weeks in hospital and whose urine contained no acetone, was put on diabetic diet for 24 hours. Nine hours later a faint trace of acetone was present, which became very marked after 17 hours, and extremely marked with a trace of aceto-acetic acid after 23 hours.

CASE 2.—A female, aged 5 years, who had recovered from chorea after having been 11 weeks in hospital and whose urine contained no acetone, was put on diabetic diet for 24 hours. After 17 hours acetone was present, and it became very marked with a trace of aceto-acetic acid after 30 hours.

Examples are also seen in cases of general starvation, and a certain number of those are found in my series; but here the acetonuria would be present on admission, and this could account for but a small number of the cases. After admission this source can be eliminated, for their diet then, in all cases, consisted almost entirely of carbohydrates for the first 24 hours, being either milk only, or rice pudding, bread and butter, and milk.

2. *Diminished Power of Absorption or Assimilation of the Carbohydrates.*

Under this heading the two cases of diabetic coma would come, but not the majority of the remaining cases, for on numerous occasions dextrose, which requires no inversion but can be absorbed at once, was administered, and without exception the acetone had disappeared in about 12 hours, whereas in similar cases which were not so treated the duration was about 36 hours longer.

3. *Inability to Digest Carbohydrates.*

We have thus found that the "carbohydrate starvation" necessary to produce the acetonuria is not caused by deficiency of carbohydrates in the diet, nor is it due to a diminished power of absorption or assimilation, therefore it follows that it must result from an inability to digest the carbohydrates in the diet.

The carbohydrates of the diet given consist of two forms, lactose or milk sugar and cane sugar, both disaccharides, and starch, a polysaccharide. Before absorption can take place these must be converted into monosaccharides. This change takes place in the small intestine, lactose and cane sugar undergoing inversion, and giving as a result dextrose and galactose, and dextrose and levulose respectively, and these can be absorbed as such. Starch requires a more lengthy process, first undergoing digestion which produces maltose and dextrin, next these are inverted to dextrose, and absorption can then take place. A more elaborate process is thus necessary to prepare starchy foods for absorption than is required in the case of milk, and anything interfering with digestion should give more marked results in those fed on starches than in those getting milk. In other words, in the case of children under 2 years, whose diet is almost entirely milk, the percentage of those developing acetonuria should be lower than in those over 2 years, who are having a starchy diet, and this is just what one finds.

Under 2 years of age specimens from 99 cases were examined. and of those 47 per cent. developed acetonuria, whilst in specimens examined of children between 2 and 9 years, 68 per cent. gave a positive reaction. The minimum percentage, 41 per cent., was found in children under 1 year, the maximum, 84 per cent., occurring between 3 and 4 years.

The "carbohydrate starvation" thus being due to an inability to digest the carbohydrates, it was next sought to ascertain the cause of this temporary derangement. Naturally the disease from which the child was suffering was thought of as a cause, and an analysis was made of its prevalency under two groups: 1. According to the system affected. 2. In certain well-defined diseases.

1. *According to the system affected.*—(*a*) Diseases of the digestive system, including stomatitis; œsophageal constriction, two cases; pyloric stenosis; diarrhœa, acute and chronic; cirrhosis of liver; intestinal parasites; and abdominal tuberculosis, &c. Of 99 such cases 63 per cent. had acetonuria. (*b*) Diseases of the respiratory system, including pneumonia, lobar and lobular; pulmonary tuberculosis; pleural effusion, serous and purulent; foreign body, &c. Of 168 such cases 62 per cent. had acetonuria. (*c*) Diseases of the circulatory system, including congenital and acquired heart disease. Of 59 such cases 61 per cent. had acetonuria. (*d*) Diseases of the nervous system, including meningitis, various forms; mental deficiency; chorea; poliomyelitis; myopathy, &c. Of 123 such cases, 65 per cent. had acetonuria. (*e*) Diseases of the urinary system, including nephritis, acute and chronic; calculus; pyelitis, &c. Of 46 such cases, 63 per cent. had acetonuria.

The remarkable uniformity of the percentage under the different systems at once negatived the idea that the acetonuria was in any way due to the disease from which the child was suffering.

2. *In certain well-defined diseases.*—The same fact became evident when one analysed certain of the more prevalent diseases—e.g., pneumonia and broncho-pneumonia, 67 per cent.; tuberculosis, all forms, 62 per cent.; and the rheumatic group, 60 per cent. In fact, the only exception found was in the case of typhoid fever, and such cases showed a remarkable decrease in the percentage that developed acetonuria. I have records of 13 cases, occurring over a period of three years, and of these 2 only, or 15·3 per cent., gave a positive reaction. This fact is, I think, of considerable help in the differential diagnosis of typhoid fever, which is often very difficult in children, especially as Widal's reaction is frequently not positive until convalescence has been established. Further, the presence or absence of fever, which Pawlow[1] has shown diminishes the digestive secretions and might thus account for the derangement, seemed to have no effect, for in cases where fever was present (e.g., tuberculosis, pneumonia, &c.), and in those in which there was no fever (e.g., myopathy, cerebral diplegia, chronic nephritis, &c.), the percentage remained about the same, whilst in the case of typhoid fever it was markedly diminished.

The acetonuria, therefore, was not influenced at all by disease. What, then, was the cause? We have seen that it tended, in the majority of cases, to come on after admission to hospital; that it lasted about three days; that it occurred more frequently in children over 2 years than in those under that age—i.e., it was more marked in those who had before admission received the more complex diet and in whom the change of diet after admission would be greater than in those who were getting a simple diet, chiefly milk, both before and after admission; and, finally, that it was unaffected by disease. It remained, therefore, to inquire into the effect of change of diet. Such an investigation gave very instructive results and afforded the most satisfactory explanation of its occurrence.

[1] Pawlow: The Work of the Digestive Glands, 1902.

The most complete data were obtained in the case of children under 1 year of age. Of such cases I had more or less definite information regarding the diet before admission in 49 instances. Eleven had been breast-fed until admission and were then put on milk and water, the milk being in some cases peptonised, in others "humanised," and in yet others citrated. Every one of these cases developed acetonuria, and it disappeared in the usual way. The remaining 38 cases had been bottle-fed before admission, the chief food used being milk and barley water. Of these, 6 only, or 15 per cent., developed acetonuria.

Here, then, I believe lies the explanation of this temporary acetonuria, for in cases where a change in the diet was made acetonuria resulted; in those in which no change, or but little change, was made acetonuria was comparatively rare. Further, in children under two years the diet before and after admission was more closely allied than in children over that age, and the percentage was lower in consequence. Another factor which would also keep it lower at this age I have already drawn attention to—namely, that the carbohydrate was in the form of a disaccharide, and therefore more easily dealt with. When, however, we look at the case of children over 2 years we find a markedly higher percentage, and here the carbohydrates are chiefly polysaccharides, and the change in diet would thus be greater. It is thus apparent that mere change of diet in childhood is sufficient to bring about carbohydrate starvation and the resulting acetonuria, and that this is caused by a temporary failure of digestion in those cases. Further, as the accompanying chart shows, the change is more marked the younger the child, and there is a steady diminution in this defect as age advances. That it is greatest in

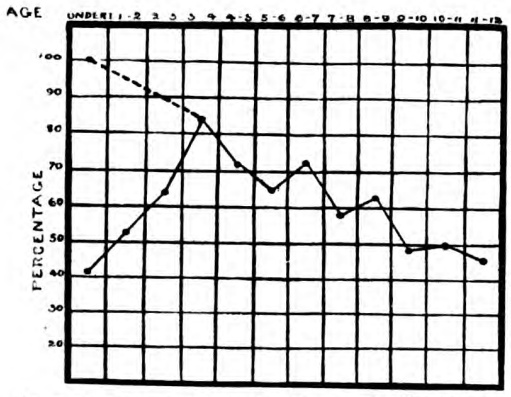

Chart showing percentage of acetonuria at different ages. The dotted line is drawn from the percentage in babies who had been changed from breast feeding to artificial feeding.

the youngest cases is shown by the fact that 100 per cent. develop acetonuria when the diet is changed from human milk to cow's milk. The comparatively low percentage under 3 years of age is not due to an absence of this defect, but is explained by the fact that there is less change in the diet given before and after admission at that age than at any other.

Lastly, as to the association of acetonuria with gastro-intestinal disturbance, it has been shown by Macfadyen[2] that if absorption of the carbohydrates does not take place in the small intestine the sugars are liable to undergo acid fermentation from the bacteria always present in the intestine, with the formation of acetic, lactic, and butyric acids, &c., and that these may cause irritation of the intestines, with the production of diarrhœa, &c. Thus the gastro-intestinal disturbances and the acetonuria may be explained by one and the same cause—viz., the digestive derangement—and the one is not necessarily a result of the other.

Conclusions.

1. That acetonuria occurs in childhood with great frequency.

2. That in the large majority of cases the carbohydrate starvation necessary for its production is caused by a temporary failure of digestion.

3. That this loss of digestive power can be brought about by mere change of diet.

4. That it is more easily set up the younger the child, and that the digestive instability becomes less marked as age advances.

5. That about three days are required before the digestive processes can accommodate themselves to a change of diet.

6. That disease, with few exceptions, has no influence on the production of acetonuria in childhood.

EXPERIMENTS ON THE CAUSATION OF BERI-BERI.

(PRELIMINARY COMMUNICATION.)

BY E. A. COOPER, B.Sc.,

AND

CASIMIR FUNK, PH.D.

(*From the Lister Institute of Preventive Medicine.*)

THE conclusion that beri-beri was due to a diet in which rice bulked too largely was arrived at by Wernich,[1] Van Leent,[2] and Takaki.[3] Acting upon this conclusion the latter, by modifying the diet of the sailors, has succeeded in practically eradicating the disease from the Japanese Navy. The vast amount of epidemiological evidence collected by Braddon[4] showed conclusively that beri-beri was associated with the continuous consumption of a diet composed too exclusively of decorticated (polished) rice. Braddon's observations brought out the further important point that natives, whatever their race, consuming rice which had been parboiled previous to removal of the pericarp (such as that used by the Indian Tamils) were not in danger of contracting the disease. One difference between these rices consists in the amount of subpericarpal layer remaining on the grains after the various manipulations to which they have been subjected prior to consumption.

An important fact for the investigation of beri-beri was the discovery of Eykman[5] that a polyneuritis in birds (fowls and pigeons) analogous to the human beri-beri is induced by a diet of polished rice, whereas fowls fed on undecorticated rice remained healthy. Eykman also showed that the latter variety of rice could cure fowls suffering from polyneuritis induced by a diet of the former. The next advance was due to Grijns,[6] who showed that the addition of pericarp and subjacent layers removed during decortication (polishings) to the diet of decorticated rice prevented the occurrence of polyneuritis. Neither Eykman nor Grijns adopted the simpler interpretation of their facts that beri-beri was a disease due to the deficiency of some essential dietetic constituent in the decorticated rice, but suggested that the endosperm contained some poison, the antidote to which occurred in the cortical layers removed by polishing.

The solution of the problem has been materially advanced by the work of Fraser and Stanton.[7] These authors having confirmed the preventive and curative results obtained with polishings sought to separate from them the active substance. They extracted the polishings with 0·3 per cent. HCl and precipitated the extract with alcohol. By this means the greater portion of the phosphorus was removed in the form of phytin. By the suitable addition of this phytin to a diet of polished rice they failed to prevent in birds the occurrence of polyneuritis. The alcohol extract, however, possessed protective properties. The alcoholic extract contained proteins, but these were found to be devoid of action. The inactivity of the alcohol-soluble proteins has since been confirmed by Chamberlain and Vedder,[8] who found that the dialysate of the alcohol-soluble fraction contained the active substance.

Schaumann[9] has recently published a comprehensive study of the subject containing the results of many interesting and important experiments undertaken during the past three years. Schaumann's results may be briefly summarised as follows: 1. Inorganic phosphates had no curative properties. 2. Phytin, which had been credited by Aron[10] with some preventive properties, gave entirely negative results. 3 Complex mixtures, such as yeast, rice polishings, Katjang-idjoe beans, if administered in sufficient quantity to pigeons far advanced in the disease, produced a cure. 4. Although an impure

commercial sample of yeast-nucleic acid cured the disease in 3 out of 14 cases (pigeons), it was not possible to obtain conclusive results with all kinds of simple phosphorus-containing substances, such as lecithin, glycerophosphates, and phospho-proteins. For these reasons Schaumann suggests (*l. c.* p. 347) that phosphorus compounds can only exercise curative effects when acting in conjunction with certain other substances.

With this we conclude the *résumé* of the more important work on the problem of beri-beri and pass to the consideration of the results of our own experiments.

We have repeated feeding experiments of former workers upon birds (fowls and pigeons) with the various kinds of rice and have confirmed them, and have also confirmed the preventive action of rice bran (polishings). Experiments with an exclusive diet of various pure carbohydrates—starch, inulin, cane sugar, and dextrin—have been carried out, and it was found that such diets induced polyneuritis with the usual symptoms. These results disprove any intoxication hypothesis concerning beri-beri in birds. A daily ration of 0·5 gramme phytin administered to pigeons fed on white rice did not prevent polyneuritis, and attempts to cure polyneuritis by the addition of phytin, edestin, casein, and egg-yolk were unsuccessful. As the latter two substances are relatively rich in organically combined phosphorus the negative results are important. One gramme of dried pressed yeast per day prevented the development of polyneuritis in fowls, and we were also able to confirm the curative properties of pressed yeast. Yeast-juice obtained by squeezing the ground cells with kieselguhr in a press was found to exert a curative effect like the original yeast. *We have also found that pressed yeast hydrolysed with 20 per cent. sulphuric acid for 24 hours still retained its curative properties.* As all organic phosphorus compounds are completely hydrolysed under such conditions, and phosphoric acid has been shown to be without influence, it is very improbable that the polyneuritis is the result of a deficiency in phosphorus compounds.

After confirming the results of Fraser and Stanton concerning the beneficial effects of the alcoholic extract of rice polishings, we precipitated a water solution of the extract by means of phospho-tungstic acid, and found that the active substance is precipitated entirely by this reagent and that the filtrate is completely inactive.

The curative effect of the precipitate decomposed by baryta in the usual way, which is wholly devoid of phosphorus and also free from carbohydrates or protein groups, was tried upon ten pigeons; it was found to be extraordinarily active and cured the birds even when they appeared moribund, striking improvement occurring in from three to ten hours. In several instances birds which were completely paralysed and supposed to be dying in the evening were found next morning with but some trace of lameness.

Polishings appear to contain only a very small amount of the active substance, and for further progress a very large quantity of polishings must be dealt with.

In conclusion, it appears that the polyneuritis induced in birds by a diet of decorticated and polished rice is not due to the deficiency of phosphorus compounds, but to the absence of some substance not of protein nature, devoid of phosphorus, soluble in water and acidulated alcohol, dialysable, and precipitated by phospho-tungstic acid, and the precise nature of which is being at present investigated by one of us (C. F.).

We are glad to have this opportunity of expressing our best thanks to Dr. C. J. Martin, F.R.S., Director of the Lister Institute, for drawing our attention to this subject, and for help and advice in the course of the investigation; and to Dr. Leonard Braddon of Seremban, Malay States, to whom we are indebted for kindly furnishing an adequate supply of different kinds of rice and rice polishings.

A NOTE ON THE CARBOLIC ACID COEFFICIENT OF DISINFECTANTS.

BY F. T. MARCHANT, M.R.S.I.,
LECTURE ASSISTANT IN THE PUBLIC HEALTH DEPARTMENT OF UNIVERSITY COLLEGE, LONDON.

THE Rideal-Walker method of determining the carbolic acid coefficient of a disinfectant often furnishes results which are discrepant—viz., a subculture tube often shows a growth when another tube, containing the same culture exposed to the same dilution of a disinfectant and for a shorter period of time, fails to do so.

It must be assumed that if the same organism in similar numbers is present, then concordant results should always be obtained; but owing to the small amount of fluid which the platinum loop employed in the process for inoculation purposes can hold (and it may also be that there is a diminution in the number of living organisms surviving the action of the disinfectant) it is quite possible that occasionally none of these may be picked up with the loop, and therefore no growth can result. To overcome the discrepancy alluded to, amongst other suggestions, THE LANCET Commissioners[1] advocated the use of a platinum spoon which would hold about three times as much inoculating material as the platinum loop. But, as they pointed out, three or four spoons must be employed; each one being used in turn after being placed on a rack to cool subsequently to sterilisation. This modification has the advantage of employing a larger dose of the organism, but it increases the danger of the diluted disinfectant containing the organism getting contaminated from outside sources. That this contamination does take place is demonstrated by the fact that organisms other than those experimented with are sometimes found in the subculture tube.

THE LANCET Commissioners also pointed out that according to their method no disinfectant had a higher carbolic acid coefficient than about 13. The probable explanation of this is, again, the fact that a larger dose of organism is added with their spoons than with the platinum loop. Also when working with the separating flask a lower coefficient is obtained than by the Rideal-Walker method as performed in the usual way.

I have recently contrived a small apparatus which works very successfully. By its employment there is no fear of contamination from the air, a large dose of the organism is added, no platinum loops or spoons are required, and the test can on the whole be expeditiously carried out. The apparatus consists of a small glass separating flask; the part above the stopcock is open to the air, cylindrical in shape, 3 in. long, and nearly 1 in. in diameter; the stem below the stopcock is narrowed down to a very fine point, so that only a very small drop of fluid can escape. The top is kept plugged with cotton-wool (which is only momentarily removed to enable the disinfectant to be added); and on making an experiment the requisite number of these small appliances are sterilised and clamped to a stand. One drop of the typhoid broth is then added, followed by 1 c.c. of the disinfectant solution; and if the worker thinks it necessary he may mix the contents by stirring with a platinum loop. The subculture tubes are inoculated at the proper intervals of time by turning the stopcock, allowing one drop to fall into the tube, and then gently shaking the tube.

When the experiment is finished the whole of the small apparatus may be washed through with a dilute acid, then thoroughly washed in water, the stopcock smeared with glycerine (not vaseline) to make it turn easily, re-plugged, and again sterilised in the hot-air oven, after which they are arranged ready for use.

It may be argued that the addition of as much as one drop of the mixed culture and disinfectant might include an amount of disinfectant which would inhibit growth in the subculture tubes; this, however, is not the case when culture tubes are employed containing about 10 c.c. of medium.

NOTE ON LEISHMANIA AND MOSQUITOES:

THE LEISHMANIA DONOVANI CAN LIVE AND DEVELOP IN THE INTESTINAL TRACT OF THE ANOPHELES.

BY PROFESSOR GIUSEPPE FRANCHINI.

From the Anolin Laboratory of Spedale Maggiore of Bologna, directed by Professor G. VANNINI.

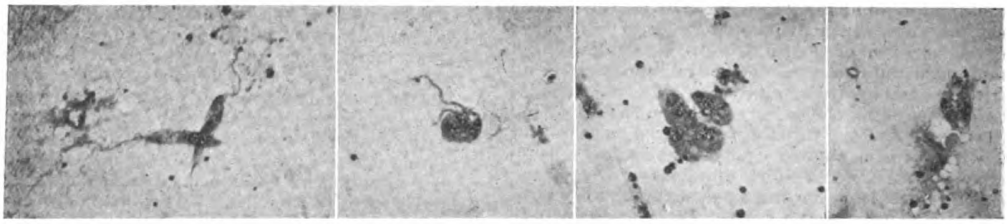
CONSIDERING the great lacuna still existing in our knowledge of the transmitting agents of Leishman's bodies, and considering the negative results obtained from experiments on cimex lectularius, pulex irritans and serraticeps, and pediculus capitis, as I have shown elsewhere, it was evident that our studies must turn to other blood-sucking insects. Starting from the fact that kala-azar often develops in malarial countries, I wished to begin my researches on mosquitoes, choosing the anopheles species (claviger variety)—that is to say, the same which has already been shown capable of transmitting human malaria.

The mosquitoes I chose came from the malarial zone of the province of Ferrara, and in a small part from that of Bologna. These were placed in vases at the bottom of which was a stratum of culture from 10 to 15 days old, pure and well developed, about as thick as a penny. Upon this was spread a disc of thick gauze adhering to the culture material. In this manner the insects could suck the culture through the gauze without contaminating it with their feet and wings. Some others, after having had the extremities of their wings cut off, were put into contact with culture placed on a moveable object glass. In the long series of experiments I could see for certain that some of the mosquitoes had fed upon the culture, because externally a sort of pink swelling was visible projecting beneath the insect's abdomen immediately below the restriction which separates the thorax from the abdomen. It was evidently a question of the so-called "ventricolo succhiatore" dilated by the liquid of the culture. The mosquitoes were then put under large glass bells and left there till their death, which took place at the most within 60 hours.

With the insects which had been in contact with the culture after half an hour, and after 1, 2, 3, 6, 8, 12, 16, 24, 36, and 48 hours, preparations, fixed in methyl alcohol and coloured with Giemsa, were made for smearing. It is needless to say that before smearing the mosquitoes had been frequently and carefully washed. Some of them were imbedded and sectioned, and I made many preparations to compare the smears and sections. I assured myself also that the leishmaniæ outside the culture tubes could live for a quarter of an hour, half an hour, and longer; and with the cultures I made smears to see which were the prevalent forms. After ½–2 hours

Series I.

FIG. 1. FIG. 2. FIG. 3. FIG. 4.



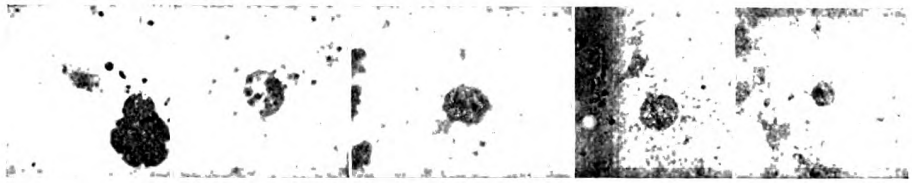


FIG. 5. FIG. 6. FIG. 7. FIG. 8. FIG. 9.

Explanation of the Figures.—Figs. 1 and 2 represent flagellated leishmaniæ of the digestive tube of the mosquito within the first three hours. Fig. 2 is evidently about to divide. Fig. 3 after about five hours; in one leishmania a slight flagellum is still evident. Figs. 4 and 5, aflagellated leishmaniæ of the elongated form met with within the 12 hours. Figs. 6, 7, 8, and 9, leishmaniæ of different dimensions with very clear nucleus and blepharoblasts and chromatic granulations met with within the 24 hours. All the microphotographs have been taken with a two-millimetre Zeiss objective, aperture 1·30, homogeneous immersion, and a Zeiss compensating eyepiece No. 4. Length of tube 160 millimetres. Bellows of the apparatus opened to 43 centimetres.

Series II.

FIG. 1. FIG. 2. FIG. 3.

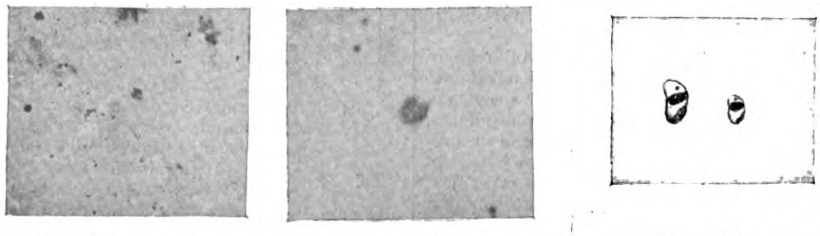

Fig. 1. Magnification as Series I. Fig. 2. Compensating eyepiece No. 12 was used. Fig. 3 represents two illustrations made with a Zeiss microscope, homogeneous immersion—the first with compensating eyepiece No. 4 and the second with compensating eyepiece No. 8. They represent forms of small Leishman bodies with nucleus and blepharoblast as in the organs of patients suffering from kala-azar, and as met with after 24, 36, or 48 hours.

I could observe in the smears from the intestine numerous leishmaniæ in great part flagellated with well-coloured protoplasm, nucleus, and blepharoblasts. In some rare forms the pale protoplasm presented vacuoles, some were in division, presenting two flagella, protoplasm with large well-coloured granulations, two nuclei, and two very clear blepharoblasts. In from 5–8 hours the flagellated forms were very rare, and where they existed the flagellum was short and the leishmaniæ had taken in part a more globular form, but without signs of degeneration. After 10–12 hours the Leishman bodies were less and less common, with light blue protoplasm and well-coloured nucleus and granulations and without flagella. Near these, other forms were evidently degenerating. After this period of time I have never seen elongated forms of leishmaniæ, but roundish ones, some big, others smaller, very rare, with visible nucleus and blepharoblasts, and with grains of chromatin. After 24–36–48 hours I was able to observe small forms, still very scarce, with nucleus and blepharoblasts of the identical form and structure of Leishman's parasites which are met with in the hematopoietic organs of those suffering from kala-azar illness. I made some smears with the dejecta of mosquitoes which had certainly sucked the culture for a relatively short time, and in two preparations I met with two typical leishmaniæ of the elongated form, sufficiently well preserved but without flagella. The above experiments were made at a temperature which varied from 28° to 30° C.

In conclusion, I claim that the leishmania donovani can live and develop in the digestive tube of the anopheles, at least in those of the above-named districts. I think I can affirm this, because if it were not so the parasite would be destroyed in a short time by the digestive juices of the mosquito and by the numerous bacteria. The leishmaniæ themselves, on culture outside the tubes and in their own liquid, although protected from their external surroundings, only live for a short time. Smears of bugs and fleas (dog fleas and human fleas) which had certainly sucked, when fixed and coloured, even after a quarter to half an hour, have not presented any form which could resemble leishmaniæ even from afar. They were evidently destroyed as soon as introduced. My experiments on this subject have been recently confirmed by Basile of the laboratory of Grasse. That leishmaniæ could develop I deduce from the most varied forms observed in preparations of mosquitoes, making comparisons with the smears from the cultures. Moreover, in cultures of 10–15 days there could not be the small forms which I met with after 36–48 hours, and which appear only in tubes of very old culture.

These results appear to me of great importance if we remember that the "flora batterica" is very abundant in the digestive tube of the mosquito, and that the leishmania donovani in culture *does not develop if the medium is contaminated, nor can it live long when any contamination supervenes in an already well-developed culture.* Note again the tendency of the leishmania shortly after its introduction into the mosquito to lose the flagella and become aflagellated like the forms which live in human organism.

I wish these researches of mine to be made known because they are new and may open a fresh field of inquiry on the agents (insects) which transmit kala-azar. These, in short, are the results I have obtained; other studies are requisite, and, in part, have already been begun. It is necessary, in order to determine in which part of the digestive tube the leishmaniæ live best and undergo modifications, to inject emulsions of infected mosquitoes into animals, and to put these in cages with close metallic network together with susceptible animals. By putting the mosquitoes in larger spaces than those I employed, and by feeding them also with blood, it will not be difficult to make them live longer than I succeeded in doing.

UNIVERSITY OF SHEFFIELD.—The Council at its meeting on Oct. 27th made the following appointments: (1) Mr. Percival E. Barber, B.A., M.R.C.S. Eng., L.R.C.P. Lond., to the Professorship of Midwifery; (2) Mr. Miles H. Phillips, M.B. Lond., F.R.C.S. Eng., to the post of Lecturer in Gynæcology; (3) Mr. Mackenzie Douglas, M.A., M.D. Edin., to the post of Junior Demonstrator in Pathology; and (4) Mr. P. F. Kendall, B.Sc., to the post of Assistant Curator of the Zoological Museum. At the same meeting Emeritus Professor R. J. Pye-Smith was appointed to represent the University on the General Medical Council.

DRILL AND DEVELOPMENT: A PLEA FOR UNIVERSAL MILITARY TRAINING.

BY LEONARD B. CANE, M.D., B.C. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

LIEUTENANT, ROYAL ARMY MEDICAL CORPS (TERRITORIAL FORCE); SURGEON ATTACHED TO INNS OF COURT OFFICERS' TRAINING CORPS; ASSISTANT PHYSICIAN TO THE PETERBOROUGH INFIRMARY.

THE value of organised drill and discipline has long been recognised in our public and national schools, and has recently received additional acknowledgment from those responsible for the formation and rapid growth of lads' brigades, boy scouts, and similar organisations. That these are of benefit in developing the physique and to some extent the characters of their members is undoubted; in fact, were it not so it would be difficult to account for the widespread support they have received from all quarters. Such results must be attributed, not only to the healthy exercise which is so prominent a feature of the training, but also to some extent to the organised drill and the habits of obedience and collective action which are thereby acquired, and which cannot fail to have some influence upon character in after-life. Mr. J. L. Hughes, who as inspector of schools in Toronto has had for more than 30 years exceptional experience in noting the effects of drill in the Toronto Schools, considers that "during their period of adolescence boys' moral natures may be developed by drill more definitely than by any process of teaching. ..... It develops them physically, and gives them freedom and grace of step, and a manly and dignified bearing. It trains them to be responsively obedient and ..... defines in a boy's mind a consciousness of the need of coöperation. ..... Drill makes boys executive, and executive training is the highest training. I sincerely hope," he writes, "that the boys of the whole Empire may be encouraged in every legitimate way to learn military drill for their own development, and to qualify themselves for their duty as citizens."[1] To ensure the best results, however, organised drills and other training of a military nature should be incorporated in the school course and be made compulsory on all. Otherwise the training will too often be avoided by just those weaklings who require it most. Its permanent value would be greatly increased if every boy on leaving school and before settling down to earn his living had to pass through several months of camp training on lines similar to those laid down for the Territorial Army. All who have had charge of the health of Territorial units must have been favourably impressed by the great improvement in health noticeable after only a fortnight's training, and many must have regretted that similar opportunities were not open to all. The extension of physical drill systems in schools, followed by a short period of military training for all youths of sound physique, would do much to raise the standard of national health, and arrest the acknowledged tendency towards physical deterioration.

The object of this brief article is to show, without reference to detailed statistics, the immense improvement in development that may be expected from even a few months' military training, and to strongly advocate that some such system should be universally adopted in this country. It will be shown that even a few months' training results in marked improvement, not merely in muscular growth but in weight, chest measurement, and general development, and it is clear that such progress must be accompanied by strengthening of the whole body and increased resistance to disease. "Military service," writes Dr. Erich Wellmann, "improves and hardens the physical condition and the efficiency of recruits, puts an end to habits injurious to health, and gives the soldier who passes into the reserve the stamp of a strong, healthy, and agile man. Thus the individual soldier has his health improved, and through him the improvement is communicated to the nation."[2]

In this country but few opportunities for noting the effects of a short course of military training upon large numbers of men have hitherto been available. The following brief extracts from various British and foreign sources may, however, serve to indicate some of the results that may be expected. In 1906 the *Spectator* raised an "experimental company" of 100 men for a six months' course of military training. The men were selected almost at random, and "represented all classes of the community. There were two

sons of clergymen, one yeoman farmer, one son of a shopkeeper, several clerks and shop assistants, three club servants, one stevedore from the London Docks, one sailor, sundry artisans, and a large majority of labourers. The average age on enlistment was 19 years and 10 months, the ages ranging from barely 17 up to 24. The average height on joining was 5 ft. 7¾ in., the chest measurement 35 in., and the weight 134 lb. At the end of the course the average height was 5 ft. 8¼ in., the chest measurement 36¾ in., and the weight 140½ lb. Hard work during the very hot weather brought down the weight, which at the end of three months had been 142 lb."[3] More recently some recruits who had joined together were measured on enlistment and again after eight weeks' training. The results in every case showed an improvement, the increase in height varying from ¼ to ½ in., in weight from 11 lb. to 16½ lb., and in chest measurement from ½ in. to 1¼ in.[4]

At the annual meeting of the British Medical Association in 1904 some instructive statistics from foreign sources were given by J. Ellis Barker,[5] which showed conclusively the excellent results obtained in comparatively short periods of military training. In the German Army 392 men were measured on four occasions—on enlistment, and after four, 7½, and 12 months' service. The increase in capacity of the lungs after successive periods of training was remarkable; on joining the army 16·6 per cent. were found to have a lung capacity of from 2000 to 3500 c.c.; 67·3 per cent. with capacity from 3500 to 4500 c.c.; and 16·1 per cent. with capacity of 4500 c.c. and over. At the end of four months' service the percentage of men with lung capacity of less than 3500 c.c. had fallen to 9·9 per cent, with a corresponding increase in number of men with larger lung capacities, 70·4 per cent. having from 3500 to 4500 c.c., and 16 8 per cent. from 4500 c.c. upwards. After seven and a half months' service this improvement was continued, only 8 per cent. of the men having still the low capacity of from 2000 to 3500 c.c., whilst those with capacities of 4500 c.c. and over had risen from 16·1 per cent. (on joining) to 26·4 per cent. After this period additional progress was but slight, the proportion of men in the three classes at the end of the year being approximately that found after seven and a half months.[6]

In the French army similar measurements taken by Dr. Frilley (6435 men) showed that after only six months the average height had increased by 0·1 in., the weight by 3¼ lb., and girth of chest by ½ in.[7] In the Japanese Army detailed annual statistics show clearly that the greatest improvement takes place during the first year of service, and that after that period there is but little further progress.[8] In the United States detailed measurements of recruits at Columbus Barracks show the following changes after a course of about three and a half months' instruction: average gain in weight, 2·81 lb.; average gain in chest expansion, 0·6 in.; average gain in size of chest inflated, 0·65 in.; also increase in size of muscles of the arm, and a diminution in waist measurement.[9]

These and similar extracts show conclusively that even a few months' military training is responsible for definite and well-marked progress in physical development. Not only this, but the enforced discipline and regular habits cannot fail to be of benefit and to prove of distinct value in after life. Dr. A. Shadwell, in "Industrial Efficiency" (vol. ii., p. 406), referring to the universal service in Germany, states that he has "met with no two opinions about its educational value to the individual and its industrial value to the nation. Perhaps the most striking effect is the physical benefit derived from the exercises, drill, gymnastics, and regular life. It turns a weedy anæmic lad into a well-knit, upstanding young man with sound organs and well-developed limbs. It further teaches him cleanliness, discipline, order, authority, self-respect, and respect for others. The effect in the workshop is visible at every turn. It is not too much to say that military service has been in a great measure the making of industrial Germany. Employers and employed have gone through it together; they have learned in the same school, and they equally understand that order is essential to every organised force, industrial as well as military."[10] It is interesting to note that at Krupp's work at Essen a man who has been through his training earns 2*s.* a week more wages than one who has not. As Blatchford says, "A training which produces such results is good for any youth, and the nation would be richer materially and morally if every English boy could be so trained."[11]

The very moderate proposals brought before the House of Lords by Lord Roberts in July, 1909, would if adopted be quite sufficient to ensure a lasting improvement in national physique with consequent increase in mental and moral fitness, and capacity for work in all classes of the community. The National Service Bill provides for a *single* continuous course of from four to six months' training for every able-bodied youth between the ages of 18 and 21 (with certain necessary exceptions), to be followed in the next three years by a fortnight's training in camp with the Territorial Army (and liability up to the age of 30 to be called out for home defence only in case of national danger).

With the military aspects of this scheme it is not my purpose here to deal. Suffice it to mention that it is estimated that about 150,000 youths would be available for training every year, so that in a few years' time we should have prepared a potential army of a million men for home defence. From a health point of view, however, I am convinced that in universal military training we should find a partial solution to one of the greatest problems of to-day; and that with its introduction into this country an effective check would be given to the progressive deterioration in national health. The definite increase in weight, strength, and lung capacity which I have shown may be expected would be accompanied by general improvement in health and power of resistance to disease, and at the same time habits of discipline, cleanliness, and healthy living would be acquired, which in many cases would persist throughout life and prove of permanent value both to the individual and to the state.

It is to emphasise the value of compulsory drill in schools and to advocate the adoption of universal military training in this country that this article has been written.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Two New Major Operations.—Exhibition of Cases and Specimens.

THE first meeting of the session was held on Oct. 20th, Mr. H. LITTLEWOOD, the President, being in the chair.

The PRESIDENT delivered an address, taking as his subject Two Major Operations devised by himself—namely: (1) interscapulo-thoracic amputation; and (2) supra-trochanteric amputation of the femur. 1. The interscapulo-thoracic amputation differed entirely in principle from Professor Berger's operation, in which the subclavian vessels were ligatured as a preliminary step; in the operation now described the vessels were exposed and secured as they were met with during the course of the operation. A cervico-scapular flap was first turned back, the scapula and the muscles attaching it to the spine were exposed, and the muscles divided. The clavicle was next divided near the sterno-mastoid attachment by a Gigli's saw. The whole limb now fell away from the trunk, putting the brachial plexus and the subclavian vessels on the stretch, so that they stood out and could easily be seen. The brachial plexus was divided with scissors, and first the axillary artery, then the vein, was clipped with forceps and divided. The anterior or pectoro-axillary flap was now cut and reflected as far forwards as necessary, the pectorales were divided, the fore-quarter was removed, and the flaps were sutured. Mr. Littlewood had performed the operation in 25 minutes. He claimed that it was a much shorter and easier method than Berger's operation. 2. Supra-trochanteric amputation of the femur, which could either be done for trauma or sarcoma of the lower end of the femur, was

performed in the following manner. The patient was brought to the top of the table, resting on the sound side. Two flaps were cut, an antero-internal and a postero-external, the length of each corresponding to one-third of the circumference of the hip-joint. The antero-internal was first marked out and turned up for about two inches, and the femoral vessels were exposed and ligatured. The muscles were divided and the neck of the femur was exposed. The postero-external flap was next cut and the muscles were divided; last of all those attached to the great trochanter. The capsule was stripped up from the anterior intertrochanteric line for half an inch without opening the hip-joint. A Gigli's saw surrounded and divided the neck of the femur close to the inner side of the trochanter. The limb was now removed. The smaller vessels were secured as soon as they were divided. It was suggested that this operation should be performed in certain cases instead of the regular amputation at the hip-joint, a moveable, and so more useful, stump being formed; it was also thought the shock might be less. Recurrence after sarcoma generally took place in internal organs and not in the stump. It was not likely to recur in the head and neck of the femur, the bony parts left in this operation. In the cases operated on in this way there had never been any recurrence in the stump. The operation was first performed in 1897. Mr. Littlewood strongly advocated the method of securing the main vessels at the point of division in forming the flaps and deprecated the use of tourniquets. The subject of shock was fully discussed, and the ethics of performing major operations in difficult and doubtful cases were considered. Two patients were shown on whom the operations had been performed.—A vote of thanks was proposed by Mr. PRIDGIN TEALE, seconded by Dr. A. G. BARRS, and supported by Mr. LAWFORD KNAGGS.

Dr. BARRS showed a case of Acute Infective Poliomyelitis in a boy aged 16. All four limbs were involved in a complete loss of use without sensory disturbance, but with total loss of reflexes. The faradic reaction had not disappeared at the end of a month, and would probably not now be lost.

Dr. T. WARDROP GRIFFITH showed a case of Poliomyelitis with Paraplegic Distribution of the Palsy in a man of about 24. The symptoms had been ushered in by pains, and there had been some transitory affection of the sphincters. There was complete palsy of the lower extremities without any vestige of sensory affection; the muscles were flaccid, the reaction of degeneration was present, and the deep reflexes absent. Attention was called to the alarming frequency of these cases during the last few years, to the fact that many of them had occurred in groups, and to the gravity of the prognosis. The distinction from paraplegia due to a non-discriminating myelitis was dwelt upon.—Dr. T. CHURTON said that the advantage of recognising the disease in its early stage—the second or third day—would be the isolation of the patient until all possible danger of infection was past, and also that the proposed treatment by urotropine might be put in force in the acute stage. In febrile cases occurring in young children the limbs should be closely observed by the nurse during washing operations.

Dr. GRIFFITH also showed three specimens in illustration of Combined Cardiac Valvular Lesions. The cases had been carefully watched during life, and the rhythm of the heart and the character of the venous pulse in the case of two of them showed that the condition of auricular fibrillation had been present. The influence of digitalis, the use of which had for long been of marked benefit in slowing the cardiac action and in inducing the occurrence of coupled beats, the second of which did not reach the wrist, was well demonstrated by the tracings of the venous pulse.

Dr. CHURTON showed a case of Disseminated Sclerosis of Oppenheim's Sacral Type, with anæsthesia in the second sacral root area, in a man aged 47.

Dr. C. OLDFIELD showed a patient on whom a New Radical Cure Operation for Prolapse of the Uterus had been performed. The patient was a healthy woman, 64 years of age, who had suffered for many years from complete genital prolapse. A pessary no longer gave her relief, and she pressed for radical treatment. None of the ordinary operations for this condition appeared to be suitable, and so a new operation was designed. After complete resection of the uterus and vagina, followed by shortening of various ligaments of the uterus and vagina and the uniting of corresponding ligaments of the two sides, the margins of the levatores ani were sutured from just behind the urethra as far back as the anus, and finally the superficial muscles and fasciæ were approximated. No shock or trouble of any kind followed, and the successful immediate result, with a substantial and unyielding pelvic floor, suggests that the patient has obtained a true radical cure.

Cases and specimens were also shown by Mr. H. COLLINSON (with Dr. J. B. HELLIER), Dr. ALEXANDER SHARP, and the PRESIDENT.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Liverpool on Oct. 20th, Dr. J. B. Hellier, the President, being in the chair.—Dr. Hellier related the history and showed the specimen of a case of Carcinoma of the Cervix, complicated by pregnancy and treated by abdominal panhysterectomy. The operation necessitated the division of one ureter which was subsequently implanted in the bladder. The patient made a good recovery.—Dr. W. E. Fothergill (Manchester) described the case of a patient whose first pregnancy ended in early abortion. Early in her second pregnancy abortion was threatened, and it was found that the uterus contained three fibroids, one on either side and one behind, which occupied the pelvic cavity. At the sixth month there was an attack of pain and fever. The pregnancy continued, however, until within a week of time, when the membranes ruptured without the onset of labour. The child was delivered with forceps after manual dilation, and after the fibroid which occupied the pelvis had been pushed up. The patient's pulse and temperature remained normal for six weeks after the confinement, when pain, fever, and vomiting occurred. Supra-vaginal hysterectomy was done, and the fibroids were all found to contain pus. Dr. Fothergill also showed the corpus uteri and both appendages removed from a virgin, aged 42, by the abdominal route on account of pain of long standing and hæmorrhage which remained excessive after curetting. The organs were buried in adhesions, and the patient's old pelvic peritonitis doubtless dated from an attack of appendicitis with suppuration, which was relieved by operation in 1902. The uterus contained a fibroid polypus of the size of a hazel nut, which accounted for the hæmorrhage. Its existence was not suspected.—Dr. Arnold W. W. Lea related a case of Fibromyoma which obstructed labour at full term in a multipara, aged 36, with a history of four previous deliveries. She was admitted to hospital during labour, the membranes having ruptured. The cervix admitted two fingers, but was pressed back to the sacrum by a large myoma occupying the pelvis and reaching to the level of the umbilicus. The child lay in the upper portion of the uterus. As delivery through the vagina was impossible Cæsarean section was carried out, followed by supra-vaginal hysterectomy. The child was living and weighed 6½ lb. The patient made an uneventful recovery.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on Oct. 20th.—Dr. R. Barclay Ness showed a boy, aged 10 years, who during the past ten months had suffered from an unusual series of manifestations of acute rheumatism. Eight weeks before admission to the Western Infirmary he had had a mild attack of rheumatic arthritis affecting the larger joints of the arms and legs, and five weeks later subcutaneous nodules appeared in various situations. On admission in February last these nodules were found to be the fibroid nodules commonly associated with the rheumatism of childhood; they were situated in the neighbourhood of the small joints of the hands and of most of the larger joints of the arms and legs, and in the occipital region. In the latter site they were as large as green peas; elsewhere they were much smaller. The boy also presented evidence of endocarditis. He was dismissed apparently well, except for a valvular lesion, at the end of March. A month later he was readmitted with severe chorea accompanied by another crop of nodules similar to the first. Two months later, when still in hospital, he developed pericarditis and left-sided pleurisy, with reappearance of nodules a little later. This illness almost proved fatal, but by the end of a fortnight all immediate danger from the pleurisy and pericarditis was over. His convalescence was interrupted on two occasions, when he was allowed out of bed, by a slight return of the chorea. The nodules reappeared towards the

end of August and had persisted since then, though gradually diminishing in size. The chief interest of the case lay in the long series of rheumatic manifestations, which included within ten months articular rheumatism, subcutaneous fibroid nodules, endocarditis, pericarditis, pleurisy, and chorea.—Professor R. Stockman, in a paper on the Vaccine Treatment of Gonococcal Arthritis, reviewed the literature on the subject, from which it appeared that while some observers had written enthusiastically of the curative results of vaccine treatment in all forms of gonococcal infection others had found it valueless. He then reported the results obtained by vaccine treatment in nine cases of urethritis or vaginitis with arthritis. The gonococcus was isolated in every case, and autogenous vaccines were mostly, but not exclusively, used. In all cases the treatment was at first exclusively by the vaccine, but in most cases no distinct improvement followed, and ordinary local treatment was added or substituted. This was always followed by immediate and distinct improvement in the local and general conditions, and to it cure was finally due. In only one case did recovery take place under vaccine treatment alone, but improvement was so rapid and marked after only one dose of 5 millions as to be hardly attributable, in view of the results in the other cases, to the vaccine. In two cases fresh joints became infected while the vaccine treatment was being given, which should not have happened had the vaccine been capable of conferring immunity or even of increasing substantially the resistance to infection. Comparison of these results of vaccine treatment with the results of ordinary treatment by means of copaiba given internally and local applications led to the conclusion that the administration of dead gonococci exerted no curative influence on gonococcal arthritis. The reaction that followed a sufficient dose of vaccine could be used as a method of diagnosing gonococcal infection, but its variability seriously impaired its value.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The autumn meeting of the Northern and Midland Division of this society was held at the kind invitation of Dr. E H. O. Sankey at Boreatton Park, Baschurch, Salop, on Oct. 19th, Dr. Dawson, the President, being in the chair.—Dr. Pierce, in a paper entitled "Some Remarks on the Diploma in Psychological Medicine," pointed out that four universities—Edinburgh, Durham, Manchester, and Leeds—had already instituted a diploma in psychological medicine and that others were seriously considering the subject. After giving a brief *résumé* of the curriculum required at the various schools, he said he thought it might safely be concluded that the new diploma had come to stay, and would in time take a position corresponding to that held by the D.P.H. He went on to show how the new departure would affect those engaged in the treatment and care of the insane, improving their status. At present the position of assistant medical officers in asylums was highly unsatisfactory, many of them being obliged to live celibate lives and having little or no recognised legal status. He thought the association should point out to county councils and others engaged in lunacy administration the importance of the diploma.—An interesting discussion followed, in which the President, Dr. Sankey, Dr. White, and others took part. The general feeling was one of agreement with the points brought forward in the paper.—Dr. Sankey then read a short paper introducing the subject of the Treatment of Acute and Early Cases of Insanity, with special reference to the number of patients in asylums. He was forcibly struck, he said, with the fact that the recovery rate was nearly stationary. He considered that asylums were too big, and that in future building should be in the form of hospitals or receiving houses for acute or curable cases; that all cases should be first admitted to these, and that the failures and incurable cases only should be transferred thence to the asylum. He thought that the smaller number of patients under care with a large medical and nursing staff would result in more recoveries.—Dr. White, Dr. Cox, and Dr. J. Middlemass took part in the discussion, and reference was made to the fact that some large county asylums had hospitals for acute cases attached to them.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—The committee of management has arranged for the reception of paying patients at the Northwood sanatorium. Applications should be made to the secretary, at the offices, 7, Fitzroy-square, London, W.

Reviews and Notices of Books.

Biographical Reminiscences of Sir Samuel Wilks. London: Adlard and Co. 1911. Pp. 200. Price 3*s.* 6*d.* net.

Sir Samuel Wilks, one of the most widely known and deeply respected of the veteran leaders of our profession, has written in his biographical reminiscences, which have just been published, a memoir of a very interesting and, as might be expected from the personality of its author, of a very original sort. The memoir does not aim to give a mere personal account of the author, indeed, the purely autobiographical record is all contained in three short pages. It is rather, what the author terms it, his medical history; that is to say, that Sir Samuel Wilks has recorded the personal part which he has played in the development of medicine during an active career as hospital physician and consultant authority between the years of 1851, when he took the Membership of the Royal College of Physicians of London, and 1901, when he retired from the practice of his profession full of honours at the ripe age of 77. The 50 years over which his biographical reminiscences extend, we need hardly point out to our readers, were years of continuous progress in scientific medicine, and especially has that progress been made in the direction of morbid anatomy. The microscope, for example, was not used for the benefit of medicine and in the diagnosis of disease until shortly before Sir Samuel Wilks became a medical student, and then only in a limited manner. We are inclined to forget, having regard to the part played by the microscope in the study of modern bacteriology, that what we should now term quite coarse pathological changes were absolutely misunderstood or unrecognised before the use of the microscope became a matter of clinical routine, and that until this use was established the meaning of perfectly obvious pathological processes was unrevealed to medicine. Sir Samuel Wilks's method in writing this book of his personal medical biography has been to go steadily through the Guy's Hospital Reports, and through our columns and those of our contemporaries, and observe firstly how far he had a personal knowledge of any interesting conditions recorded, and secondly (although he is too modest to say it in so many words), how far his own work in ward or post-mortem room led to accepted conditions of medical knowledge. We can see throughout that he was in some of our most important pathological departures a vigorous and clear-sighted pioneer. In the special references which he makes to certain cases of Bright's disease, Addison's disease, Hodgkin's disease, pernicious anæmia and syphilis, his method has been to select from the Guy's Hospital Reports cases recorded by various distinguished members of the staff—for example, the great Bright, Astley Cooper, Wilkingson King, Bransby Cooper, Golding Bird, Norman Chevers, Addison, Gull, Hilton, Pavy, and S. O. Habershon. In all the pathological conditions of these cases, many of which at the time that the notes were taken must have been quite obscure, Sir Samuel Wilks had something to say that was entirely original, and whether the researches started with himself, or whether they owed their origin to the acumen of his colleagues, his comments are equally uncompromising as well as illuminating.

He records the work which he himself did on the syphilitic affections of the internal organs as the most noteworthy, and in the end the most fruitful of his observations. It must be remembered that when Sir Samuel Wilks joined Guy's Hospital as a student, although post-mortem examinations were made for the purpose of ascertaining the nature of the disease from which the patient had died, the number of such examinations was much smaller than that made now

while the autopsies were conducted far less thoroughly and without the same intention to found upon them a scientific system or to collate any findings with investigations undertaken at other times or places. The autopsies were made as a rule only in isolated instances of what appeared to be specially interesting cases; the result found on the post-mortem table was regarded as the answer to a difficult question that had been set in the wards, and the physician went to look at what the pathologist had to show him in much the same spirit as that in which a boy, having done a sum, looks at the end of the book to see if he has solved the problem aright. But Sir Samuel Wilks, who at the very outset of his career at Guy's Hospital felt himself attracted towards the subject of morbid anatomy because it offered something more positive than did the symptoms of disease, regarded no time as wasted which was spent in the post-mortem room, if only because the sedulous and systematic comparison of clinical symptoms with post-mortem discoveries must be the way of all ways to produce accurate treatment upon broad lines. As showing how much work remained to be done when he began his medical career, he records that when he first examined the body of a man who had died from syphilis he could find no account in medical literature of such an examination having been previously made, while the results of the necropsy were a complete revelation to himself as he had never expected the internal organs of a body could be affected in the manner that later came, largely through his work, to be described generally as lardaceous degeneration. A very interesting passage in the book refers to a paper published by the author in 1856 on "Lardaceous Disease and Some Allied Affections," the subject being pursued some nine years afterwards in a communication connecting the lardaceous condition with the cachexia of protracted bone trouble. The alliance of these conditions had been previously pointed out by Thomas Hodgkin in a paper read before the Royal Medical and Chirurgical Society in 1832, and when Wilks was credited with a new discovery he alluded to Hodgkin's paper, and was responsible for affixing Hodgkin's name to the condition known as Hodgkin's disease.

We have said enough to show that Sir Samuel Wilks's professional reminiscences contain matters of interest, not only to all pathologists, but to all members of the medical profession who like to regard their work in a philosophical spirit, to trace its progress, see its errors, and note the manner in which real success follows intelligent failure, and in which grave disappointment waits upon hasty presumption. We have here the notes of an actual observer upon Jenner's classical differentiation between typhus and typhoid fever, with a contribution by the author to the perfecting of this distinction; an excerpt from what Sir Samuel Wilks believes to be the first paper ever written upon excision of the joints (the paper was written for the Guy's Hospital Reports for 1833 by a Mr. Blackburn, a pupil of Aston Key); a description of four cases of cæcitis, showing that the condition now generally, and as Sir Samuel Wilks suggests inaccurately, known as appendicitis, had been well described by Addison in 1836—Sir Samuel Wilks considers Addison's account as excellent as any to be found in modern treatises; some interesting remarks upon the tests for albumin in urine; notes on Addison's disease, Hodgkin's disease, pernicious anæmia, Jacksonian epilepsy, and phosphorus poisoning, and records of the only two fatal cases of nicotine poisoning reported in this country.

We do not attempt to give the contents of this fascinating book in more detail; many of our readers will assuredly read it for themselves with profit, interest, and amusement. If a further edition is called for we plead for the inclusion of an index. It is true that the book only contains 200 pages, but the pages are closely packed.

Municipal Chemistry. Edited by CHARLES BASKERVILLE, Ph.D., F.C.S., Professor of Chemistry and Director of the Laboratory, College of the City of New York. New York and London: McGraw-Hill Book Company. 1911. Pp. 526. Price 21*s.* net.

THIS is a very interesting book containing a series of 30 lectures by experts on the application of the principles of (chiefly) chemistry to municipal matters.

The lectures were delivered at the College of New York City last year, and the course was authorised by the Honourable Board of Trustees of the College, the public being invited to attend. Each lecturer was an admittedly distinguished exponent of the subject, and the ground covered proved so interesting that it was decided to collect the lectures for publication in book form. Where no preparation had been made for publication especially prepared articles on the subject of the lecture were substituted. The result is, as we have said, a very interesting book, dealing with matters of the greatest importance to the citizen. The editor contributes an admirable article on Sanitation and the City; Dr. Pitt Mason, in two articles, deals with Drinking Water and Disease, and Purification of Water; Mr. Douglass Flinn writes on Municipal Water-supply; Dr. Thomas C. Darlington on Milk; Dr. Harvey Washington Wiley on Food Adulteration; Mr. William Allen Hamor on Food Inspection; Dr. Virgil Coblentz on Drugs and their Adulteration and Methods of Detecting Adulteration; Dr. Lyman F. Kebler contributes an article full of common-sense writing on Habit-forming Agents. Then follow Streets and their Construction and Modern Road Construction, both by Dr. Allerton S. Cushmann; Street Sanitation, by Mr. William H. Edwards; Methods of Street Cleaning, Waste Disposal, by Edward D. Very; the Disposal of City Sewage, by C. A. E. Winslow; Making Illuminating Gas and the Valuation of Illuminating Gas, by Dr. Arthur H. Elliott; the Smoke Problem, by Dr. Payn B. Parsons; Ventilation, by Dr. Herbert R. Moody; the Chemistry of Personal Hygiene, by Dr. Thomas A. Storey; Textile Materials and their Service to Man, by Louis A. Olney; Combustibles and Explosives, by A. A. Breneman; Paint, Iron and Steel, Cement and Concrete, by Maximilian Toch; and Parks, Gardens, and Playgrounds, by Dr. Nathaniel Lord Britton.

We have not met with a more interesting collection of authoritative opinions on these special problems of the city. The way in which medicine, chemistry, and engineering are coping with numerous problems under each of these headings is admirably exemplified throughout the pages. The work is a very practical and important contribution to the sanitary sciences.

Essays and Clinical Studies. By F. G. CROOKSHANK, M.D. Lond. London: H. K. Lewis. 1911. Pp. 245. Price 7*s.* 6*d.* net.

IN these days of systematic text-books, statistical articles, and experimental research, the art of essay-writing upon matters of clinical interest is in some danger of becoming a lost one. Dr. Crookshank has collected together in this little book a number of essays which he has published at various times in periodical medical journals. They have been written, as he explains in his preface, "in the odd moments allowed by the pre-occupations of general practice and the duties of public appointments." They cover a wide range of subjects, but all are of interest, and show evidence of careful thought and observation.

The first is entitled "Ramazzini and His Book." This is the only one of the essays devoted to medical history, and it deals

with the "De Morbis Artificum," which contains a number of acute observations upon diseases of occupation. Certain aspects of insanity are then considered by Dr. Crookshank in a series of notes and short essays. He lays considerable stress upon the physical signs of mental disease, and makes suggestions for the treatment and management of insane patients that should be valuable to general practitioners in regard to the early stages, which come usually under their notice. Among these essays upon the subject of insanity is one in which the frequency, causation, prevention, and treatment of phthisis pulmonalis in asylums are considered, and suggestions are offered as to the separation of tuberculous from non-tuberculous patients and as to the establishment of asylum-sanatoriums.

The next notes and articles are on the subject of the diagnosis and treatment of pulmonary tuberculosis, which Dr. Crookshank prefers to call phthisis; indeed, he somewhat unkindly alludes to those who use the more scientific term as "arrogantly superior persons." His only ground for preferring the older name appears to be that "pulmonary phthisis is not only a tuberculosis, but a septic necrosis as well." We are not conscious of any arrogant assumption of superiority, but there appear to us to be many advantages, not least of which is that of convenience and uniformity, in adopting the etiological designation of the condition.

Scarlet fever and diphtheria are discussed in another series of papers. The isolation hospital is defended as the most satisfactory method of dealing with cases of the former disease and as a means of reducing its incidence. Dr. Crookshank describes a system of bed isolation which he has employed and found of great value in avoiding the troubles incidental to isolation hospitals, troubles which he regards as entirely preventable. Dr. Crookshank's views on these points have been commented on at length already in our columns.

One of the most interesting and valuable of the essays is the concluding one on the examination of bodies found in the river. This contains many useful hints and practical suggestions. There are also a few notes or papers dealing with general subjects, to which specific reference need not be made.

Dr. Crookshank possesses a keen critical faculty and a philosophical turn of mind which accepts nothing on trust. He has a pleasing and easy, though at the same time incisive, literary style. His book is interesting and suggestive, and though his readers may not always agree with his contentions, they will probably realise that they are the outcome of honest and careful thought.

Pediatrics. By JOHN ZAHORSKY, Clinical Professor of Pediatrics, Medical Department, Washington University. With an Introduction by E. W. SAUNDERS, M.D., Emeritus Professor of Diseases of Children, Washington University. London: George Keener and Co. 1911. Pp. 284. Price 10*s.* 6*d.*

THIS little book is written for the practitioner in the form of a series of golden rules which cover the ground of diagnosis, prognosis, hygiene, infant feeding, and treatment. Each sentence is practically an aphorism in itself, and it would be difficult to discover elsewhere in medical literature a more sententious and axiomatic series of apothegms. We in this country are accustomed to aids and breviaries for the immediate purposes of examination and for the ultimate confusion of those who attempt to put their contained knowledge into practice, but this book of aphorisms comes under a totally different category. It would be of little value to the student as an aid to examination, whereas we are of the opinion that it would be of very great value to the practitioner as enabling him to crystallise the knowledge that he has acquired in the days of his studentship and exercised in the practice of his calling.

Not only is the book good reading, but it is so well arranged as to facilitate reference at a moment's notice. All those who purchase a copy can be strongly recommended to commit the more important of these golden rules to memory. There are very few statements made by the author with which we find ourselves in disagreement. We do not, however, consider the diagnosis of disease in infants as easy, nor do we regard enlargement of the thyroid as an uncommon phenomenon in children. Also, the statement that laryngospasm coming in repeated attacks is most commonly symptomatic of tetany is confusing. Both these conditions are manifestations of a hyper-excitable state of the nervous system—commonly called spasmophilia—but neither of them is symptomatic of the other according to the view of present-day authorities.

It is satisfactory to note that the psychological factor is not forgotten, either in treatment or in prognosis, and in the section on the nursing mother the statement that if the mother is to produce good milk her own personal taste must be consulted commands approval. The amounts of food stated to be requisite for normal infants are much too large; an infant 9 months old does not require three pints of fluid in the 24 hours, no matter what be the degree of concentration or dilution of its solid contents. The faults, however, of Dr. Zahorsky's book are few and its virtues manifold; and it is a book that doubtless will be improved and polished with each of the many new editions which may be expected for it.

Die Massenverhältnisse des Herzens unter Pathologischen Zuständen. Von SOFUS WIDEROE. Christiania: Jacob Dybwad. 1911. Pp. 142. (Price not stated.)

THIS investigation on the size of the heart in different pathological conditions was carried out in the hospital at Christiania. The scope of the work, which is based on the examination of a large amount of pathological material, will be best understood by quoting the chief questions dealt with. The author devotes over 30 pages to a consideration of the size of the heart, its relations, and its physiological variations, and deals also with the relative size and weight of the individual parts of the heart. The special or pathological part includes such subjects as hypertrophy and dilatation, and the changes effected by chronic conditions, such as cachexia, adiposity, pulmonary tuberculosis, kyphoscoliosis, chronic renal disease, arterio-sclerosis, valvular disease, and chronic pericarditis. The author also deals very briefly with changes of the heart in acute diseases and the condition of the heart in experimental hydræmia. The table of literature is very full. The whole investigation will prove interesting and useful to pathologists.

Disease in Bone and its Detection by the X Rays. By EDWARD W. H. SHENTON, M.R.C.S. Eng., L.R.C.P. Lond., Senior Surgical Radiographer, Guy's Hospital. With illustrations. London: Macmillan and Co., Limited. 1911. Pp. 72. Price 4*s.* 6*d.*

IT is not sufficient for the purpose of diagnosis merely to obtain good skiagrams of diseased or injured bones; it is necessary that the surgeon should be able to interpret the appearances presented. The light of nature is not sufficient, and even a good knowledge of anatomy needs supplementing by a practical knowledge of X ray pictures. In this work by Mr. Shenton, who has had a very extensive experience in X ray photographs, are given a number of actual skiagrams of injured and diseased bones, and in the text he discusses the appearances seen, and explains their significance. The amount of callus formed around a fracture depends in great part on the maladjustment of the fragments, and Mr. Shenton points out that fractures treated by Mr. Arbuthnot Lane by "plating" show hardly any callus. A good skiagram of a normal hip shows clearly the "diagnostic line" first

described by Mr. Shenton; it is of much importance in recognising injury or disease of the hip-joint. This book is useful, and though it contains 46 skiagrams we cannot help wishing for more.

Lehrbuch der Pathogenen Mikroorganismen. Die Pathogenen Bakterien. Für Studierende und Aerzte. Von Dr. PAUL V. BAUMGARTEN, Professor der Allgemeinen Pathologie und der Pathologischen Anatomie an der Universität Tübingen. Mit 85 zum teil farbigen abbildungen und 1 steindrucktafel. Leipzig: S. Hirzel. 1911. Pp. 955. Price, paper, 24 marks; half bound, 26.50 marks.

THE students and physicians for whom, as set forth in the title, this book has been written owe a deep debt of gratitude to Professor Baumgarten. His classical "Lehrbuch der Pathologischen Mykologie" appeared more than 20 years ago, and the present work, which in some sense may be regarded as a new edition of the older book, has been undertaken because the author holds that such a point of clearness and unanimity with regard to the problems of immunity and infection has now been reached that their presentation in text-book form is more than justified. The material available has been compressed as much as possible, but notwithstanding this the present volume is limited to a consideration of the pathogenic bacteria. A second volume dealing with the pathogenic moulds and protozoa is, however, promised, and to its appearance all students will look forward with eagerness.

The task of the reviewer of such a work lies chiefly in a presentation of the plan adopted by the author in dealing with his material. The literature of the subject occupies, as was to be expected from Professor Baumgarten, an important place. Each chapter is followed by a carefully selected bibliography. The general arrangement of the book does not differ strikingly from that of the usual text-book. The first third is occupied by a consideration of general problems and general methods of research, while the remainder deals with individual micro-organisms. There are throughout, however, a crispness of statement and a critical weighing, in the light of very full knowledge, of the evidence bearing on the problems dealt with, which are of the utmost value to those for whom the work is intended, and even the specialist will be grateful for the opinion of such an authority as Professor Baumgarten. The problems of immunity are treated as part of a general consideration of the action of agents inimical to micro-organisms, and the chapter which begins with the effects of chemical and physical agents and deals with disinfection ends rather unexpectedly in the subject of immunity and immunisation. In dealing with disinfection we may warn the reader that the author uses the terms disinfectant and antiseptic in a sense differing from that used in English works; "kolyseptics" are the equivalents of our antiseptics.

In his treatment of immunity it is hardly necessary to say that it is the theory of Ehrlich rather than that of Metchnikoff which finds favour with the author, and indeed he allots to the phagocyte a very minor part. It is suggested, in fact, that even the strictly antitoxic sera possess a bacteriolytic activity, though one easily destroyed and difficult to demonstrate. Agglutinins are considered to possess a constitution more closely allied to that of a cytolysin than of an antitoxin, and they may possibly be identical with precipitins. Valuable chapters on immunising methods and on the demonstration and valuation of immune substances follow; cholera and diphtheria are used as examples of the method. Serum diagnosis occupies an important place. Practical directions for carrying out the investigations are given, with examples drawn from the most usual and suitable cases. The subject of opsonins meets with full recognition.

The special part of the book has some individual features. The organisms are grouped according to their pathological relationships without regard to their morphology. The primary division is into blood and tissue parasites, and these are further differentiated into obligate and facultative. The obligate tissue parasites are subdivided into toxic and infective organisms, and these latter into groups characterised by their exudative or proliferative activity. The first place is therefore occupied by the spirilla found in diseases of the relapsing and African tick fever type, and these are followed by the group of hæmorrhagic septicæmias. It is suggested that possibly the M. melitensis has the same lack of connexion with Mediterranean fever that the B. suipestifer and B. suisepticus have with the diseases in which they are found, but the evidence, especially that drawn from immunity, is of a much less cogent character. There are excellent and long sections on cholera and tubercle; the latter occupies a hundred pages, and various aspects of the subject are dealt with. The facultative blood parasites, with which the book closes, are the pneumococcus, the B. anthracis, and the spirochæta pallida.

This is a book of reference for all who want an authoritative opinion on bacteriological problems. There are many illustrations, none of them photographic, and many of them are well known and have become classical.

LIBRARY TABLE.

Dispensing Made Easy. By W. G. SUTHERLAND, M.B. Aberd. Fourth edition, revised by F. J. WARWICK, B.A., M.B. Cantab., M.R.C.S. Eng., L.S.A. Bristol: John Wright and Sons, Limited. Pp. 102. Price 3*s.* 6*d.* net.—This little volume has involved a good deal of work to make it trustworthy, and the busy practitioner will recognise its value as an aid in quick and accurate dispensing. A reference to it saves time, and the formulæ are of the approved modern type. We have noted one misprint on p. 95, where alcohol is spelt alcodol. We note also that under "Points Worth Remembering" a suggestion made by us in a previous notice has been adopted.

Urine Examination Made Easy. By THOMAS CARRUTHERS, M.A., M B., Ch.B. Glasg. Second edition. London: J. and A. Churchill. 1911. Pp. 47. Price 1*s.* 6*d.* net.—This book is primarily intended for nurses, the methods described being of the most elementary description and the ultimate diagnosis being left to the physician. The nurse, by following the clear directions given, can render a useful preliminary account of the case. The chemical testing of urine offers obvious pitfalls to the uninitiated, and the author is right in insisting upon careful observation and accurate description. On the whole, he does not expect or ask too much, and when a result of doubtful or serious significance appears the direction is, "Refer to doctor."

Forty-Seventh Annual Report of the Boston City Hospital, including the Report of the Superintendent, Feb. 1st, 1910, to Jan. 31st, 1911, inclusive. Published by the City of Boston Printing Department. 1911.—In this report attention is called to the approaching completion of a pathological histology, written from a biological point of view and based on an analysis of the material collected in the hospital during the past 14 years. Reference is made to four papers, two of which were read in May, 1910, before the American Association of Pathologists and Bacteriologists, of which publication is promised in the *Journal of Medical Research*, and two which were published last year in the *Journal of the American Medical Association*. A fifth paper, read in November, 1910, before the Johns Hopkins Hospital Medical Society, gives an analysis of many cases of cirrhosis of the liver, and opens up several important points. It shows that, apart from cancer, five different types of lesions, due to as

many varieties of causes, may lead to cirrhosis. While alcohol is the most common cause, bacterial infection among the bile-ducts, especially in children, may bring about a typical form of cirrhosis, which in later stages causes ascites and death. It has also been found that the alcoholic type of cirrhosis is characterised by a peculiar form of hyaline degeneration of the liver cells preceding necrosis. Among other points suggested in this group of five papers is the fact that the disappearance of the liver cells in the centres of the lobules around the hepatic veins is due, not to pressure, as is ordinarily taught, but to a central necrosis of toxic origin. Under ordinary conditions these necrotic cells are fully restored by regeneration, but such regeneration is prevented when chronic passive congestion is present. Also the peculiar type of cancer known as rodent ulcer has been found to arise from a hair matrix, and to be characterised by the production of epithelial fibrils, which in the hair fuse together, become hyaline, and form the hair shaft. It is further stated that the so-called giant-cell sarcomata are not tumour cells at all, but foreign body giant cells, due to the fusion of endothelial leucocytes attracted into tumours, and other lesions involving bone, by dead bone, which needs to be dissected and removed. They are identical with the osteoclasts of normal bone, which arise in the same way. The importance of this fact is pointed to in the case of epulis, which is often not a true tumour, but only a tumour-like mass of inflammatory tissue containing giant cells around disintegrating particles of bone or lime salts. In such a case, it is stated, thorough curetting would seem to be all that is required.

Plague at Home and Abroad. The Annual Public Lecture on the "Laws of Health" delivered at the Midland Institute, Birmingham, Oct. 6th, 1911, by DAVID FRASER HARRIS, M.D. Glasg., D.Sc. Lond., F.R.S.E., Professor of Physiology in the University of Halifax, N.S.; formerly Lecturer on Physiology in the University and on Hygiene at the Midland Institute, Birmingham. Birmingham: Cornish Brothers, Limited. 1911. Pp. 17. Price 3*d.* net.—This interesting lecture has a value of a wider scope, doubtless, than was originally contemplated. By its detailed account of the way in which the various steps in the knowledge of plague have been acquired, it should serve the two-fold purpose, firstly, of enlightening the public generally on those apparently mysterious methods of science, concerning which they are usually so hopelessly ignorant—an ignorance that is the cause of most of the obstruction to the application of the scientific measures of preventive medicine; and, secondly, of increasing the public respect for the profession of medicine. It is through the study of the methods of scientific medical research as exemplified in the growth of knowledge about such diseases as plague, malaria, yellow fever, sleeping sickness, and others, that the confidence of the public in the medical profession will be maintained. This little pamphlet, therefore, can be cordially recommended by any of our readers to their patients and friends for general perusal.

Off the Main Track. By STANLEY PORTAL HYATT. London: T. Werner Laurie. 1911. Pp. 293. Price 12*s.* 6*d.* net.—A series of vivid pen pictures of men, manners, and things, principally in connexion with South Africa, are here presented by a writer who shows much sympathy with the native races and is rather impatient with British rule. Some 30 illustrations add to the value of the book. In view of the "fly crusade," the writer's theory that flies may be responsible for the spread of venereal disease is interesting. "Whenever," he says, "a Mashona has an open sore, due to any cause whatsoever, he lies in the sun and allows the flies to get at it ..... whilst the flies are afterwards permitted to settle where they like—on food, in the corners of babies' mouths, anywhere." Whether or not syphilis is conveyed in this way, the danger arising from such a condition of things is sufficiently obvious.

JOURNALS AND MAGAZINES.

Edinburgh Medical Journal.—The October issue of this journal is the annual "Educational Number," containing some 30 pages on the facilities for medical training in Scotland. Dr. D. Berry Hart writes on Enzygotic Twins—that is to say, twins derived from one zygote or fertilised ovum, the condition being due to doubling of some of the "determinants." Dr. J. H. Harvey Pirie and Mr. A. A. Scot Skirving deal with Intranasal Carcinomata, and Dr. D. W. Currie and Dr. Edwin Bramwell describe a local epidemic of Acute Poliomyelitis. Mr. J. W. Struthers records an unusual form of Diverticulum Ilei which had formed an inflammatory mass with only a minute canal persistent in the centre; and Mr. George Robertson discusses two cases of Acute Dilatation of the Stomach following Gastro-Enterostomy, and caused by undue narrowing of the jejunum in the operation.

Dublin Journal of Medical Science.—This (October) number also is "Educational." The original matter consists of the Review of Vital Statistics for Ireland, delivered by Sir W. J. Thompson as his presidential address at the Royal Institute of Public Health Congress, Dublin, and published in abstract in THE LANCET of Sept. 16th.

Birmingham Medical Review.—In the current number of this magazine Dr. W. J. McCardie continues his review of the Present Position of Spinal Analgesia. He concludes that it occupies a middle position between inhalation and local anæsthesia. "Generally speaking ..... it should only be used in certain selected cases." Dr. A. Douglas Heath records an epidemic of Groin Ringworm in a school, and Dr. William H. Wynn contributes an interesting critical review of the curious phenomena known as Anaphylaxis and Serum Disease, of which the true nature is little understood at present, but which are gradually being brought into relationship with a number of diseases and morbid symptoms.

West London Medical Journal.—The October issue opens with a forecast by Mr. McAdam Eccles of the future of surgery, in which he puts in a plea for the supply of more plentiful material for dissection and for the practice of operative surgery classes. Mr. Leonard A. Bidwell writes enthusiastically on the immediate and ultimate results of gastro-enterostomy for gastric and duodenal ulcers, holding that all cases of the latter condition should be operated on at once, and of the former as soon as medical treatment shows any sign of lack of success. In the discussion which followed his paper some doubts were expressed as to the general need of such drastic procedure.

Caledonian Medical Journal.—The opening article in the October number of this journal is the presidential address delivered by Dr. J. L. Waters at the annual meeting of the Caledonian Medical Society held in Hull on Sept. 23rd. He took for his subject Certain Features of Celtic Life and Story, illustrated with ample details relating to anthropology, history, and questions of politico-social organisation. Dr. Lachlan Grant of Ballachulish, Argyleshire, gives much salutary advice in a contribution entitled "Home, Sweet Home," which in its original form was a health lecture delivered to women and girls in Oban.

Annals of Tropical Medicine and Parasitology.—Issued by the Liverpool School of Tropical Medicine. Series T. M. Vol. V. No. 2. August, 1911.—The editor of these Annals is Professor Sir Ronald Ross, K.C.B., F.R.S., and the first item in the present number is an "In Memoriam" notice, with portrait, of the late Sir Rubert Boyce, F.R.S., himself a

former editor of the publication. After this, Professor Umberto Gabbi furnishes a short but interesting "Note on Tropical Diseases in Southern Italy," in which he refers more particularly to Mediterranean fever and kala-azar. Professor R. Newstead then contributes an article on "Papataci Flies (Phlebotomus) in the Maltese Islands"; this has been reprinted from the *Bulletin of Entomological Research* and is profusely illustrated. The article is in reality the report of the twenty-third expedition sent out by the Liverpool School of Tropical Medicine. Professor Newstead, in collaboration with Mr. Henry F. Carter, assistant entomologist, also writes a second paper on "Some New Species of African Mosquitoes (Culicidæ)," with illustrations. Captain R. McCarrison, I.M.S., a high authority on the subject of the etiology of bronchocele, gives a valuable paper on the "Experimental Transmission of Goitre from Man to Animals," with illustrations. Two eminently scientific papers are contributed by Dr. W. W. Yorke and Dr. R. W. Naus of the Runcorn Research Laboratories, the first being on "The Reducing Action of Trypanosomes on Hæmoglobin," and the second on "The Mechanism of the Production of the Suppression of Urine in Blackwater Fever" (illustrated). This last-mentioned paper, we believe, was read in the Tropical Medicine Section at the annual meeting of the British Medical Association in July last at Birmingham. Dr. J. W. W. Stephens gives an account of "The Anti-Malarial Operations at Ismailia" (with 2 maps). The next article is the first report of the expedition sent out in 1911 to Gambia by the Liverpool School of Tropical Medicine; it is furnished by Dr. J. L. Todd and Dr. S. B. Wolbach, and is entitled "The Diagnosis and Distribution of Human Trypanosomes in the Colony and Protectorate of Gambia." The last of these interesting contributions is one upon which we have already made some comments in the columns of THE LANCET of Oct. 14th; it is by Dr. G. C. E. Simpson and Mr. E. S. Edie, B.Sc., and its title is, "The Relation of the Organic Phosphorus Content of Various Diets to Diseases of Nutrition, particularly Beriberi." This number of the Annals contains a large amount of important, as well as varied and valuable, matter; the papers are well worth careful study by all who are concerned with tropical medicine.

British Journal of Inebriety.—The October number of this publication contains an article on Alcoholic Epilepsy, by Dr. Francis Hare, based on his clinical experiences as medical superintendent of the Norwood Sanatorium. Dr. Hare believes that alcohol *per se* may give rise to typical epileptic fits in individuals who have, so far as can be discovered, no tendency to epilepsy, and in his paper he summarises 13 observations in support of this view. All the patients were addicted to continuous excess, drinking chiefly spirits; there were no takers of absinthe. In every instance the epileptic attack, which was ordinarily of the type of *grand-mal*, followed a complete withdrawal or sudden reduction of the drinker's usual allowance of alcohol, the duration of the period from the stoppage of the intoxicant to the onset of the fit varying from 15 to 74 hours. In three of the cases delirium tremens developed after the epileptic seizure. From the facts observed by him, Dr. Hare draws the conclusion that alcoholic epilepsy depends primarily upon the establishment of tolerance to alcohol, and secondarily upon a sudden fall in the amount of the drug circulating in the body—in short, that it is of the nature of an abstinence symptom in chronic intoxication. He holds a similar view with regard to the causation of delirium tremens. It is Dr. Hare's experience that a patient who has once suffered from alcoholic epilepsy is likely to have convulsions on subsequent sudden cutting off of his usual supply of liquor, but he has not found that the occurrence of these fits has any tendency to set up ordinary recurrent epilepsy. This number of the journal also contains a brief *résumé* of the facts regarding the relationship of alcoholism and tuberculosis, by Dr. J. Johnston, and an account by Mrs. Bramwell Booth of the work of the Salvation Army in the care of inebriate women.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A COMITIA was held on Oct. 26th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen having passed the required examination were admitted Members of the College:—Francis Graham Crookshank, M.D. Lond., L.R.C.P., George Harold Cross, M.B. Oxon., Elkin Percy Cumberbatch, M.B. Oxon., Robert Skeoch Frew, M.D. Edin., Horace Bryden Hill, M.B. Lond, L.R.C.P., Edwin Walter Routley, M.D. Brussels, L.R.C.P., Percy Edward Walton Smith, M.B. Sydney, and John Aldren Wright, M.D. Camb.

Licences to practise physic were granted to 83 gentlemen who had passed the requisite examinations.

The PRESIDENT announced that Mr. Arthur Lloyd Davies had been appointed the nineteenth Jenks scholar. He also stated that as Sir David Bruce was unable to undertake to deliver the Croonian lectures in 1913 Dr. J. Dixon Mann had been appointed in his place.

The following communications were received: 1. From the Royal College of Surgeons of England, dated July 27th and Oct. 13th, reporting proceedings of the Council of that College upon July 27th and Oct. 12th last. 2. From the Dean of the Faculty of Medicine, Edinburgh University, dated July 27th, reporting that the Murchison Memorial Scholarship had been awarded to Mr. Walter Quarry Wood. 3. From the librarian of the University of St. Andrews, dated Sept. 28th, thanking the College for a gift of books.

A report from the Committee of Management dated Oct. 3rd was received and adopted. The report recommended that the County School, Carnarvon, and Repton School should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

The PRESIDENT reported on the celebration of the 500th anniversary of the foundation of the University of St. Andrews, and the REGISTRAR (Dr. J. A. Ormerod) read the admirable Latin address from the College which he had prepared for presentation on that occasion.

A report was received from Dr. StClair Thomson concerning the Third International Congress of Laryngology and Rhinology. The audited accounts of the College for the year ending Sept. 19th, 1911, were received and adopted.

Dr. J. A. Ormerod was re-elected a member of the Committee of Management.

The Harveian Librarian (Dr. Norman Moore) supplied a list of books and other publications presented to the library during the past quarter, and the thanks of the College were returned to the donors.

After some further formal business the PRESIDENT dissolved the Comitia.

UNIVERSITY OF OXFORD.—The following degrees have been conferred:—D.M., E. L. Kennaway; B.M. and B.Ch., J. F. Penson and E. L. Pearce-Gould.

INVALID LADIES' HOME AT CANNES.—This home is open to ladies, being British subjects, also to American ladies, between the ages of 18 and 50, who are suffering from maladies for which the climate of Cannes is recommended, whose means do not permit them to winter at Cannes without this assistance, and of whose recovery there is reasonable hope. The home is open from Nov. 1st to April 30th of the following year. Application should be made to Miss M. Husband, Hôtel des Anglais, Cannes, Alpes Maritimes, who will send the necessary form to be filled up. The charge for board, lodging, and medical attendance is 24 francs 50 centimes per week, to be paid weekly in advance. Dr. W. Gordon Sanders and Dr. Ginner are the honorary physicians to the home. Fifteen ladies can be accommodated.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 4, 1911.

Report of the Chief Medical Officer of the Board of Education.

THE annual report for 1910 of the Chief Medical Officer of the Board of Education was presented to Parliament on Saturday last. It is a document of great interest, both from the facts which it sets out, the comments upon, and deductions from, those facts made by Sir GEORGE NEWMAN, and the evident promise underlying the whole that by an adequate system of inspection of school children slowly but steadily we must improve the race. It is not so unnecessary or platitudinous as might be supposed to make the last statement, for a good many persons, some of whom ought to know better, have been found during the last two years saying that the system of school inspection implies merely the collection of a vast number of statistics, which are gathered in such a way that they can teach but little, even though their lessons be sought out, and which are destined not even to receive the necessary collating and sifting without which their utility and significance must be gone. This report contradicts such gloomy prophets succinctly. Closely written, bristling with facts, and compelled to range over large and undefined territories of medicine, sanitation, hygiene, and eugenics, the report is none the less so clearly put together that the intelligent reader, medical man or layman, can hardly fail to draw his conclusions, or to see that so far as these conclusions are definite they are based upon the results of school inspection. The net outcome of the report is to show that the vast revolution which began to take place in the care of the youth of this country when the Education (Administrative Provisions) Act, 1907, came into force has progressed on the whole in a systematic and satisfactory manner. The facts collected with regard to the administration of medical inspection and medical treatment of school children, as to their physical condition, as to the education of feeble-minded and physically defective children, as to the proceedings of school doctors, parents, teachers, school nurses, and attendance officers in their various interrelations—all the figures and the details therewith connected speak for the work accomplished; and from reading the summarised account we arrive at the view that the ameliorative phase following upon medical inspection in England and Wales has definitely begun. We say this despite the figures given by Sir GEORGE NEWMAN, who points out, speaking generally, that "out of the 6,000,000 children registered on the books of the public elementary schools of England and Wales about 10 per cent. suffer from a serious defect in vision, from 3 to 5 per cent. suffer from defective hearing, from 1 to 3 per cent. have suppurating ears, from 6 to 8 per cent. have adenoids or enlarged tonsils of sufficient degree to obstruct the nose or throat, and thus to require surgical treatment, about 40 per cent. suffer from extensive and injurious decay of the teeth, about 30 to 40 per cent. have unclean heads or bodies, about 1 per cent. suffer from ringworm, 1 per cent. from tuberculosis in readily recognisable form, from 1 to 2 per cent. are afflicted with heart disease, and a considerable percentage of children are suffering from a greater or less degree of malnutrition." This formidable category of disease and defect, with all the suffering and inefficiency therein implied, must greatly limit the capacity of the child to profit by education, while the outlook for the next generation is certainly darkened by the presence among us of so much incapacity. None the less the evils are to a great extent remediable, and now that we have taken stock of them in a systematic way and begun to combat them in many directions the prospect does not appear so very alarming. Parliament is even now engaged in an attempt to grapple with disease in the adult, and it is, as this report points out, an opportune time to remember that no insurance scheme can be effective or enduring unless it begins with the children, and particularly is this the case in relation to the prevention of tuberculosis with which we hope to deal on another occasion. No greater step could be taken by Parliament at the present time towards these desired ends than to secure that ample assistance is rendered in aid of all agencies, voluntary or State, which work for the amelioration of the children.

The machinery of medical inspection during the year has throughout the country become more homogeneous and more effective. The Act, it will be remembered, originally laid down that not only was it the duty of each local educational authority to provide for the medical inspection of children about the time of their admission to a public elementary school, but that the same inspection would have to be made on such other occasions as the Board of Education might direct. And the Board determined almost immediately that the children should also be inspected at the opposite end of their school lives; so the school population was divided into two classes for inspection—what are termed "entrants" and "leavers." In this way the local education authorities would know with what amount of mischief they had to deal, whether the methods adopted had borne fruit, and thirdly, how far the boys and girls starting in life promised well or were handicapped by physical or mental default. In addition to these two inspections 100 local education authorities undertook during 1910 an intermediate investigation, while it should be remembered that when a medical officer was making a routine inspection either of "entrants," "intermediates," or "leavers," he would be asked, as a matter of course, to examine any child who appeared to be suffering from some reason or another. The machinery of inspection has in fact begun to justify itself, and in particular Sir GEORGE NEWMAN is able to give a better report of the position of London than was the case last year. In the report for 1909 we were compelled to point out in these columns, in accordance with Sir GEORGE NEWMAN'S representations, that London lagged behind the rest of the country. The complicated difficulties under which the London County Council found

itself from the first with regard to the medical inspection of school children are well known to most of our readers, and much allowance was throughout made for the fact that the Council school children were placed at certain disadvantages, many, of course, arising out of the mere size of Greater London. There has throughout been a sincere wish on the part of the Council to meet the situation squarely, but the action taken has not been fortunate. This should now all be changed. From Sir GEORGE NEWMAN'S report for 1909 it appeared that the London Education Authority had practically failed to inspect the school children of the metropolis in accordance with the code, for out of 148,000 children comprised in the estimates of "entrants" and "leavers" only about one-quarter had been officially reported as inspected, while there had been no statutory medical inspection during that year in the vast majority of the elementary schools. During the year 1910, however, vigorous efforts were made by the authority to comply with the Act and to cope with the mass of arrears, the result being that the London County Council should in the future be able to fulfil its legal duties. It would seem from Sir GEORGE NEWMAN'S report that more than half the schools still awaited medical inspection at the close of the year, but it must be remembered that throughout the whole period the reorganisation of the medical work of the London Education Authority was going on.[1] Readers of THE LANCET know well the direction which that reorganisation has taken, and how thoroughly it is in accord with our often-expressed views. From the beginning of the movement which led up to the passing of the Act we were of opinion that inasmuch as school hygiene could never be divorced from home hygiene, the more sympathy and even combination that could be secured between the educational authority and the sanitary authority in the matter of medical inspection the better it would be for the children concerned. The view did not find universal favour, and some well-qualified speakers upon education, as all know, considered it to be a narrow one, but we believe that events have since justified the attitude which we took up, and we are glad to see that the London County Council is now of the same opinion. The Council has decided that the arrangement under which the medical charge of the school children was carried out partly by the Public Health Department, but independently by the education officer, is to be terminated immediately, inspection and treatment being coördinated and administered under the direction of the medical officer of health for the County of London. Upon the retirement, imminent and deeply regretted, of Sir SHIRLEY MURPHY from his present position as chief medical officer of the county, a new medical officer of health will supervise the whole work of medical administration in relation to education, combining in one department educational and sanitary questions. This is as it should be, and when time has allowed the reorganisation to take effect we are confident that the results will display the wisdom of the Council.

Upon the physical condition of the school children of the country, as revealed by medical inspection, Sir GEORGE NEWMAN makes remarks that will be endorsed by every thinking person when he warns us that while careful medical inspection of each individual child is the only sure foundation upon which preventive or remedial work of lasting character can be established, the process must be slow. Neither the local education authorities, nor a Government department willing to assist them in every possible way, can transform a mass of six million children, having the categorised defects to which we have already alluded, in any brief space of time into physically and mentally perfect citizens from whom the best of work and the best of descendants can be expected. The population of the country at large must work towards the desirable end. An organised system of medical inspection is the first thing; the remedies for the ills revealed come second, and for these not only is there required a proper interplay of effort between the school doctor, the school nurse, the attendance inspector, the parent, and the child, but a public intelligence of what is going on is also demanded—an intelligence that will realise how far we are from coping with disease amongst school children when we have named pathological conditions to which they are in certain proportions subject, and adopted methods more or less successfully to remedy those conditions. It is sad that so many of our State-educated children should have defects of sight or hearing. It is a serious drawback to the health of the race that so large a proportion of our boys and girls should have carious teeth. It is important, though less gravely so, that there should be a permanent prevalence of skin diseases, of adenoids, and of ringworm. These latter can be effectively treated, and the machinery for treatment is already shaping itself well; and for the other conditions an improved environment will work wonders. Over and above these definite diseases, with their definite remedies, there is the vast question of how far malnutrition, which renders so much of the school work done by the children of little account, can be dealt with. Here is where public sympathy and active coöperation is needed, and to our mind the great point about Sir GEORGE NEWMAN'S report is its cogent simplicity. Any careful reader can learn from it the vast work that has been inaugurated by the Board of Education, the progress that has been made, and in particular the numberless directions in which private individuals, by helping the medical profession to detect, to prevent, to arrest, and to remedy disease among school-children, can surely improve our race.

[1] See THE LANCET, Oct. 28th, 1911, p. 1222.

The Retiring Age.

THE problems that present themselves in considering the important matter of retirement from business vary accordingly to the sphere from which retirement takes place; but so many of them have a physiological or sociological side that it is not only to the question as affecting the medical profession that a medical paper need confine attention. From the medical profession, we suppose, not a great number of its members ever retire, in the sense that they voluntarily abandon their occupation while still in full use of their faculties. In our profession many more men die in harness than lay harness aside while still strong enough to carry it well; and the

comparatively low average age of death in the medical profession appears to show that at any given moment there is a considerably less proportion of retired members than is the case with many other callings. The work of a medical practitioner is more exacting and more exhausting than is that of a lawyer or of a clergyman, while he has not the same facilities that these latter possess of being in their profession only to the extent that they choose. An aged clergyman does not lose his benefice by delegating more and more work to a curate (if he can get one and pay one); rather his act is seen to be in the public interest. A lawyer can do his best duty while himself in unsound health; the physical grind can be left to his juniors. But with the medical man his duties are too personal for delegation and often too hard to be executed by a frail physique. Moreover, compared with his income, the medical man's expenses are proportionally high; consequently he is liable to be obliged to continue to earn an income into the late years of his life. It is in the case of general practice that the difficulty about retirement occurs, already alluded to—namely, the intimate professional relationships, which make retirement an act of desertion. This is a difficulty which, though real, has much decreased in these more hurried days. Time was when around the successful practitioner there gathered in his advancing years a body of friends, also patients, men and women who in many instances entered the world with his aid and explored the vicissitudes of childhood, youth, and maturity under his guidance. From many of these patients the family friend, being also the medical man, had received confidences which they might now be loth to impart to fresh ears. Yet without these confidences they would hesitate to entrust themselves to new hands. To withdraw his professional activity from such a circle is, in the case of a general practitioner, to inflict a very real loss upon his *clientèle*, so that even when pecuniary circumstances do not forbid it affectionate feelings may retard a medical man's retirement, though too much stress must not now be laid on such arguments. Social conditions are now much more fluid, and the number of persons who remain from the cradle till middle life always in the same locality must seldom be large enough to constitute an actual argument against the retirement of a medical practitioner.

Among those who practise along specialised lines of medicine the position more resembles that of men of other businesses and of other professions. The question of the retiring age is an important matter to them, though not perhaps of the same importance to the community. But, indeed, it might well be asked by those adopting a high moral and social standard—Ought a man to retire at all? Ought he to give up work so long as he is perfectly fit for its performance? The question cannot be answered off hand. No man has a right to deny benefits to his fellows, but a man is not always the best judge of how far the benefits that he can supply cannot be supplied equally well by others. Those who know themselves in any real sense may be trusted not to retire with undue haste or to postpone retirement to an unnecessary date. But it is the greatest possible mistake to suppose that the man who retires, whether from the feeling that his course is run or from the desire to benefit by leisure at the close of his life, has necessarily chosen the best path for himself. The accessory circumstances vary so immensely that where the course is right for one man it is certainly wrong for another. We may remember the remark of the American business man, successful and aged, to his son, who suggested that the business could now run on without the senior partner: "Yes, my lad; but the senior partner can't run on without the business." There was much truth in the old man's retort. The tremendous hold of habit has to be reckoned with. Not all men can safely and suddenly change their methods of life when they are approaching old age, and if work is an ingrained habit the enforced idleness of leisure is apt to become disastrous. Herein lies the importance of a second string to the professional bow. A well-cultivated hobby, that has grown in the garden of activity alongside the professional tree, may well shelter the retired professional man's last years, and give him just as much labour as is good for him to accomplish. Who has not seen the lack of such a resource in those perforce retired from active service? The pensioned military man, who has cultivated nothing but his profession, and knows no art but that of command, may make the family martinet, or the club bore, or both.

This question of the retirement of an active worker is not simple whether looked at from an objective or subjective standpoint. Subjectively the individual may act as best suits him and his belongings. If he "can't run without his business" he will see no reason against continuing to run with it. But suppose that business to be an already overcrowded profession. Objectively, and reasonably as it appears to them, his competitors cry, "You have enough to retire on, your family and your wants are supplied to the end. Why do you continue to fill a place that so many are waiting for by whom its advantages are really needed?" The answer must be found in a broad view. It is the greatest good that is to be sought, and that must often mean that a man should continue his distinguished work though he does not need the money it brings, and though there are others anxious to do the work instead of him. Though we may still be far from the day when the practice of medicine will become a State service, it is impossible not to see that the tendency of the times is towards such a revolution. In a State medical service compulsory retirement at an age-limit, as we have it in the navy and army, would possibly be enforced upon our profession. Our feeling is that such regulations would be highly dangerous. Youth must be served, and the wisest seniors among us are those who welcome most readily the coöperation of their juniors. But numbers of the difficulties which the public brings to medicine for solution depend for that solution upon the wisdom that is born of manifold and divers experiences, so that in many cases compulsory retirement of medical men under a system of age-limit would be a misfortune. While there is bound to be injustice and waste of good material wherever a hard-and-fast age limit is laid down for the cessation of active work by all individuals of any large body of men, in dealing with the medical profession this would be particularly the case.

Suicide in Prisons.

IN his annual report for the year ended March 31st, 1911, Dr. HERBERT SMALLEY, the Medical Inspector of Prisons, discusses at some length the question of suicide in the prison population of this country. The question is one of very great interest, not only in its possible bearing on the efficiency and humanity of prison administration and with reference to the psychology of the criminal, but also because, presenting as it does a particular case of a large and important bio-social problem, the examination of its special and distinctive features may be expected to throw light on other aspects of that problem. For this reason the facts and figures brought forward by Dr. SMALLEY have a wider significance than might be suggested by their official presentation, and are likely to appeal to the interest not only of the legal and medical professions, but to many persons who are not specially concerned with penological matters, but who have the cause of social progress at heart.

The most striking and also the most satisfactory point established in Dr. SMALLEY'S report is that in the English prisons suicide is of very infrequent occurrence. During the last ten years the number of deaths from this cause has varied from a minimum of 4 to a maximum of 14, the annual average for the whole period being 9·5, a tolerably low figure when it is borne in mind that the yearly admissions to prison average upwards of 200,000. This low rate of suicide would go to show that imprisonment *per se* has not the detrimental influence in this respect which used to be, and in some quarters is still, imputed to it. And the same conclusion is further confirmed by the extreme rarity of this phenomenon in the class of prisoners who ought more than any other to show the alleged injurious effects of incarceration—namely, the inmates of the convict prisons. It may, indeed, be argued with some plausibility that so far from promoting suicide the fact of imprisonment, which postulates the removal of the worries and disappointments incident to the struggle for existence, has quite the opposite result; and we should, perhaps, be justified in attributing to the beneficent influence of imprisonment the fact that during the last few decades suicide in prison has shown no trace of the upward tendency which until quite recently has been so marked a feature in the statistics of ordinary suicide. Whatever be the explanation, this want of correspondence in the statistical movement of suicide in the general population and in the prison population may be taken to suggest that suicide amongst prisoners does in fact present some distinct characteristics. And this impression is strengthened by a more detailed examination of the data, which shows, as Dr. SMALLEY points out, that prison suicide is marked by certain peculiarities, amongst which the most notable is a tendency to much earlier age-incidence. In ordinary suicide, as is well known, the period of maximum frequency is in the later age-groups; in fact, this predominance is so marked that on the average over 55 per cent. of male suicides occur at ages over 45, though the males above that age form only 28·3 per cent. of the total adult male population. On the other hand, amongst prisoners who commit suicide the proportion aged upwards of 45 years is only 24·4 per cent. It is true that the prison population, as compared with the general population, contains a relative excess of young adults, but the difference, even at the highest probable estimate, would certainly be quite insufficient to account for such a contrast as we have indicated. It appears likely, therefore, that the explanation is to be sought, at all events in part, in other influences dependent either on the special character of persons going to prison or the special conditions that attach to imprisonment. In this connexion Dr. SMALLEY draws attention to the highly significant fact that suicide is relatively far more frequent in the case of prisoners guilty of impulsive crimes, and more particularly of homicidal offences and of crimes against sexual morality. These are forms of delinquency which are relatively infrequent and make but a very small contribution to the prison population; indictable homicidal crime, for instance, only amounts to 2·3 per cent., and indictable sexual offences to 1·7 per cent. of the total volume of indictable crime, but they account respectively for 14·7 per cent. and 7·3 per cent. of the criminality of prisoners committing suicide. It might be suggested that, as these offences expose the delinquent to heavy penalties, the suicidal tendency may be related less to the nature of the crime than to the known or anticipated severity of the punishment which the prisoner has to face; but against this explanation we have the fact that this tendency is equally marked in the minor sexual offence of indecent exposure, which is of like impulsive character with the more serious crimes of lust, but does not usually entail more than a very short sentence of imprisonment. We may take it, then, as established that the criminals who have committed impulsive offences, and especially offences expressing morbid and destructive impulses, are those who are most prone to suicide; and as it is offenders of this same class who are also most frequently found to be, or to become, insane, it is reasonable to suspect that the suicidal tendency may be due to insanity, the impulsive act of suicide, like the impulsive crime which preceded it, being an initial symptom of mental disease. While admitting that this explanation may hold good in many instances, Dr. SMALLEY seems disposed to think that more often than not the emotional instability shown in the crime and in the suicide may be due to conditions within the limits of mental health. In this connexion the facts regarding suicidal attempts ought to be peculiarly instructive, and they certainly go to support Dr. SMALLEY'S view. Indeed, most observers who have had large experience of cases of this sort will probably agree that only a relatively small proportion of persons making such attempts are insane; the majority are suffering from alcoholism, while the residue consists chiefly of adolescents in whom such a condition of emotional instability as we have indicated is to be regarded as a physiological result of their age. And this latter fact may, perhaps, be allowed to have special significance in connexion with the tendency to earlier age incidence in prison suicide; it would go to suggest that an important factor in the causation of such suicides may be that the impressionable temper of youth allows an excess of impulsive reaction to the shock of detection or of punishment. If these inferences are justified we should be led to conclude that, in relation to suicide, imprisonment exercises a different influence, according as the individual

who has to undergo it is in adolescence or early manhood, or has reached maturity; in the former case it acts as a violent emotional shock of which the self-destructive impulse is a natural sequence, while to the grown man it is rather a temporary protection from the stresses of active life, and is, therefore, to that extent a corrective of the economic influences which play so important a part in determining adult suicide.

Whatever view be taken as to these speculative considerations, the facts embodied in Dr. SMALLEY'S report afford at all events additional and very important evidence of the desirability of taking into account their physiological condition in applying penal discipline to adolescent offenders. It may be noted as a significant fact from this point of view that no instance of suicide has been recorded amongst the youths detained in the Borstal institutions. The growth of these institutions within recent years has been a gratifying evidence of the spirit which actuates penal administration in this country. The Borstal system encourages growth of body and mind, and promotes both self-restraint and self-respect, so that it is natural, while very cheering, to know that a large majority of those who undergo it benefit permanently by the strong incentives to reform—tersely, they do well.

Annotations.

"Ne quid nimis."

THE BACTERIOLOGICAL STANDARDISATION OF DISINFECTANTS.

Two years ago THE LANCET undertook an inquiry into the comparative value of the chief proprietary disinfectants on the market.[1] The aim of THE LANCET Commission was to evolve a method which would show working figures which *per se* could be subjected to criticism. By means of special apparatus and technique the method was elaborated so that by using more dilutions a broad curve of results was shown both with the disinfectant and the carbolic acid control. It was pointed out that a comparison of greater mathematical value could be made between the two, and the liability to error, as compared with the Rideal-Walker test, was very considerably reduced; at the same time mistakes due to errors of technique were disclosed and thus could not affect the result. We are of opinion that the claims then made were justified. On p. 1267 of this issue we publish a note by Mr. F. T. Marchant, Lecture Assistant in the Public Health Department of University College, London, in which he describes a further modification of technique making for greater simplicity. He proposes to substitute a modified separating flask to hold each of the mixtures of culture and graded disinfectant solution. At the necessary intervals a drop from each of the mixtures can be allowed to pass into the tubes of subculture medium. The suggested modification appears to be a good one. It would seem, though we have had no opportunity of testing it, to be exact in its working, and should give results as consistent as those obtained with the apparatus used by our Commissioners, over which in some positions it might have advantages. For example, it is clear that with this apparatus any type of organism may be used in the test. In certain circumstances this may be a distinct gain, but it must be remembered that for the purpose of comparing different disinfectants a standard organism must be decided upon, and we still maintain that B. coli communis is the one most suitable. By Mr. Marchant's method the broad curves of results we require can undoubtedly be obtained, and we would urge him, and those who follow this method, when testing a disinfectant, to remember the importance of this point—one on which we were very insistent—and give the full curve of results on which the comparative figures are based.

[1] THE LANCET, Nov. 13th, 20th, and 27th, 1909.

A "RETURN" CASE OF SCARLET FEVER.

AN action of considerable importance to the medical officers of isolation hospitals was tried recently by Judge Ruegg, K.C., at the Hanley county court. The plaintiff was the father of a boy who had been treated for scarlet fever in the Bucknall Infectious Diseases Hospital, and afterwards at the Bagnall Convalescent Hospital. The defendant was Dr. C. H. Phillips, who in the capacity of medical superintendent to the Stoke-on-Trent and Stoke Rural Joint Hospital Board had discharged the lad from the Bagnall hospital after a period of treatment in the two institutions amounting to eight weeks. The case for the plaintiff was that his son had been negligently discharged while still suffering from the disease, and that in consequence it had been communicated to other persons, one of whom was his father, the plaintiff. The case for the defence was a denial that the patient was suffering from scarlet fever or capable of communicating it when he was discharged; that the defendant acted in his official capacity and was not personally liable; and that every reasonable precaution was taken, the treatment being proper and according to the best known and recognised methods. The facts leading up to the litigation were that on his discharge the boy was taken home by his parents in a taxicab, that three days after his return his father developed symptoms of scarlet fever, and it was further stated that the child of a customer of the father who had carried a pair of boots away from his shop (the plaintiff being a bootmaker) had also contracted scarlet fever. The original patient, the son of the plaintiff, also developed scarlet fever again, his mother giving evidence that she found him to be peeling on making an examination after her husband was taken ill. Medical evidence was given on behalf of the plaintiff as to his illness and the condition of the lad when he was medically attended for his second attack, and the medical witnesses on both sides were asked a considerable number of questions as to the sources of infection in scarlet fever and in particular as to the extent to which infection should be ascribed to desquamation. The evidence of the defendant, who stated that as medical officer to the hospital board during a period of 25 years he had had under his care over 10,000 cases, was to the effect that the case was a mild one with no complication except that during the last fortnight there had been a slight sore inside the nose, which had caused him to retain the lad at the hospital when his discharge was first suggested to him after the patient had been for six weeks under treatment. In the eighth week there had been no discharge either from the nose or ears, and slight desquamation of the heel observed at the end of six weeks had ceased. He pointed out the possibility that in the course of the removal of the child in a taxicab the subsequent catarrh of the nostrils of which there had been evidence might have been brought on, and that a return case with fresh infectivity might have been the result. The evidence of Dr. Phillips was corroborated by expert evidence given by Dr. G. Reid, medical officer for the county, and details of the boy's treatment were deposed to by nurses. His honour Judge Ruegg, who tried the case without a jury, in giving judgment, said that in order to find for the plaintiff he must be satisfied that there had been negligence on the part of the defendant,

and expressed his difficulty in understanding how the boy could have been allowed to leave the convalescent hospital if at the time of his discharge he was manifesting the symptoms that he showed almost immediately afterwards, especially as he had been detained for an extra fortnight owing to conditions which admittedly had been observed. In all the circumstances he found that there was no negligence and gave judgment for the defendant with costs. It was intimated, in response to an appeal to that effect, that the question of foregoing costs would be submitted to the London and Counties Medical Protection Society, who must be congratulated in bringing a difficult and anxious case to a just conclusion.

THE NEW CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A NEW edition of the Calendar of the Royal College of Surgeons of England for 1911–12 is now published. The name of the late Sir George Sutherland Mackenzie, K.C.M.G., has been added to the list of donors and benefactors, and the Calendar states that he left by will a sum of £30,000, the income therefrom to be paid to his two brothers for their joint lives and the life of the survivor, and, on the death of the survivor, to be paid to the President and Council of the Royal College of Physicians of London and the President and Council of the Royal College of Surgeons of England for the purpose of providing the means of assisting qualified medical persons to pursue scientific medical investigation. The Calendar contains a statement of the number of candidates who were admitted to examination during the past collegiate year for the Fellowship, to the first, second, and third examinations, and to the examination for the licence in dental surgery respectively, with the results of the several examinations. The Fellows of the College now number 1518, an increase of some 30 names from that of last year, and include 1 elected "*ad eundem*," 6 "by election," 28 elected as Members of 20 years' standing, and 1483 admitted by examination. The oldest name on the Fellows' list is Mr. Peter Redfern of Belfast, who was admitted a Fellow in 1851, and it is of interest to note that Lord Lister's name figures next on the list. He became a Fellow in 1852. The Members' list contains 16,929 names. The oldest Member is Mr. Edgar Jones, of Great Burstead, Essex, who became a Member as far back as 1834, and who is now in his 102nd year. The Licentiates in Dental Surgery and the Diplomates in Public Health are still increasing in numbers. Particulars of the various College prizes are included in the Calendar, and for the first time an extended index has been added, thereby increasing its usefulness for reference purposes.

SUPPURATION IN THE ACCESSORY SINUSES OF THE NOSE.

IN the issue of THE LANCET of last week we published a report of a paper by Mr. Herbert Tilley at a meeting of the Medical Society of London on acute and chronic suppuration in the nasal accessory sinuses. It is curious how little was known a few years ago about the diseases of these sinuses even by those who devoted special attention to the diseases of the nose. With the advances in our knowledge we have learnt in the first place how very frequently these suppurations occur, and how often their existence is entirely unsuspected. A recurring morning headache and a slight nasal discharge may be all the symptoms of which the patient is complaining, and yet for years he may have had an extensive suppuration in one or more of the accessory sinuses. Not rarely indeed the patient's health may have been so good that he may boast that he has never had a day's illness in his life; doubtless in such cases as these protective processes have been going on, with the result that he has become protected against the germs affecting the sinuses and their toxic products. Not only has our knowledge of these sinuses increased, but our power of dealing satisfactorily with them has increased also. The extent and ramifications of these accessory cavities are so widespread and numerous that it is easy to see that special skill and knowledge are required to deal with them. The antrum of Highmore is comparatively easy of access, and it is of interest to note that Mr. Tilley considers that the canine fossa is the best route by which to drain most cases of antral suppuration, and that he condemns unreservedly any attempt to drain a chronic suppuration through the buccal socket of a tooth. The frontal sinus presents difficulties greater than those connected with the antrum, and in this case the importance of a cosmetic result is greater, but it is when we consider the deeper sinuses, those of the ethmoid and of the sphenoid bones, that we are able to appreciate the skill needed in treatment. Structures of the most vital importance are almost immediately in contact with these sinuses, only a few millimetres intervene between the sinus wall and the base of the brain, and a small error in the use of an instrument may cause serious injury. At present the necessity for immediate radical operation is not urged quite so intensely as a few years ago, for it is now known that in a certain proportion of cases less energetic measures may be followed by success, yet there are cases in which rapid and thorough operation is needed for recovery.

"TOUJOURS PERDRIX."

ONE of the most interesting observations made in regard to a strict monotony of diet is that the digestive functions readily adapt themselves to it. But if, after this digestive adaptation has been established and a peaceful appropriation of certain food substances is ensured, there is introduced something new, the system breaks down. If, for example, an exclusive meat or milk diet is suddenly changed to one consisting entirely of farinaceous foods (bread or potatoes) there invariably happens a severe dyspepsia, because the kind of digestive aid which these require for digestion has not been invoked recently, and some time elapses before the particular demand is answered. In short, each kind of food demands an agent (ferment) endowed with a specific digestive force. A consideration of this fact would seem to indicate that a policy of *toujours perdrix* is often right, at all events when for some reason the diet has to be confined to particular food substances. But, of course, when such a restricted diet is called for the health of the individual is not normal. Physiological observation is not opposed to a monotony of diet, but it is reasonable to suppose that digestive adaptation would follow the adoption of a uniformly regular dietary rythmical in its variations. Persons of regular dietetic habits are often heard to say that a change in food upsets them. Dyspeptic troubles are a frequent complaint of travellers abroad where food is different and served in a different manner from what they are accustomed to. These persons are too quick to complain. In course of time a digestive adaptation ensues, and digestive troubles disappear. Successful digestion involves, however, a psychological factor. In addition to the physiological expediency of a mixed diet the relish or zest inspired by the pleasant appearance and attractive taste of food is an important quality. Without appetite the digestive process is prone to become dilatory, and when food begins to pall upon the palate it is a sign that the digestive functions are satiated also: the limit has been reached and excess has been begun. Hence the mixed diet, mixed to a reasonable extent, is a necessity,

place being found for several classes of foods, each having a distinct and separate food value, and each prompting the gastric functions to maintain an all-round digestive capacity. But the source of protein need not always be mutton, nor the source of carbohydrate potatoes, for then the pyschological factor ceases to serve, and monotony produces a true physiological revolt. Some people complain that the cycle of meat foods is a very small one, and so it is, especially with the working classes, whose choice is restricted to beef and mutton and pork. The art of cookery can, however, do much to relieve the boredom of diet, and on every ground more attention should be given to it.

ADENOIDS AND TONSILS.

IT would be difficult to mention a surgical operation more productive of benefit when efficiently performed in suitable cases than that for the removal of adenoids and tonsils. It would be equally difficult to mention one more often performed with little ceremony and with results by no means coming up to what is expected of it. This opinion has been held for some years by many men of experience and authority in the profession. The treatment of enlarged tonsils and adenoids, and of the conditions to which they give rise, has been frequently under discussion during recent years. At the Sheffield meeting of the British Medical Association in 1908 the Section of Laryngology, Otology, and Rhinology discussed this matter, and the sense of the meeting was to the effect that the benefits which it was predicted would result from the removal of adenoids in individual cases were far from being generally obtained. Some speakers attributed this failure to the operations being insufficient. Last year, when the Association met in London, the removal of the tonsils was again discussed, and one speaker stated that in a certain throat department a black list was kept of hospitals where tonsils had been removed and the patients had come for treatment owing to recurrent symptoms; the list, it was stated, was impartial and nearly every throat department in London was represented. In reply it was objected that such statistics of unsatisfactory results were of little value, because they were drawn from hospital out-patient practice, and everyone knew that in most clinics the out-patient department was so overworked and the skilled assistance so insufficient that few senior members of the staffs viewed the results with complacency. At the recent meeting of the British Medical Association at Birmingham a discussion on the treatment of chronic adhesive processes in the middle ear occasioned some appropriate remarks bearing on this matter. One speaker said that in reading the reports upon school children he had been struck by the proportion of cases in which the diagnosis of enlarged tonsils had been made without any mention of adenoids. The natural inference was that the tonsils had been removed by the practitioner, and that the more important factor, the adenoids, had been left, which was greatly to be regretted from the point of view of prophylaxis.[1] From the proceedings of the Section of Laryngology of the Royal Society of Medicine it is evident that, far from the operation being at times insufficiently extensive, too much zeal, on the contrary, has been displayed. Cases have been brought under observation presenting bands of adhesion between the Eustachian tube and the pharynx. The question arises whether they are due to disease or to traumatism. It was pointed out that a little less operative zeal in those corners might prevent a few of those cases.[2] At times cases of malformation of the soft palate and uvula resulting from the removal of tonsils and the attempted removal of the adenoids come under notice.[3] However simple the operation may appear to be, accidents may arise even in the hands of the experienced, but it would be as well for all of us to realise that the operation is by no means so simple as it looks. The lack of ceremony previously referred to has apparently attracted the attention of the laity. A lay contributor to the *British Journal of Nursing* for Sept. 23rd last, in an article on the after-care of operations on out-patients, criticises warmly the way in which children recently operated upon for adenoids and tonsils find their way, still bleeding, into public conveyances, with nothing better to mop the blood trickling from the nose than a very grimy kerchief. Many doubtless have witnessed this sight and its occurrence cannot be ignored. The author concludes her article with a practical suggestion which is doubtless already practised in some of the special hospitals. This suggestion is that "before out-patients leave the hospital after operations for the removal of tonsils or adenoids a sterilised gauze dressing shall be applied over the nose and mouth, and a regulation packet of sterilised dressings shall be provided for each patient's use." It is added that these dressings might take the form of squares of gauze for keeping clean the mouth and nose until convalescence, and that these precautions should be extended to operations on the ear. However skilfully the operation may be performed good results are jeopardised by the lack of attention to the after-care, though everyone knows how difficult it is to have the instructions for after-care carried out even when they are handed to the patient in print. Failure in realising at times the results predicted must be attributed partly to practitioners promising too much, and partly to its not being generally recognised that in cases of long standing the evils that adenoids and tonsils do live after them. It would be well if it were more commonly recognised that the satisfactory removal of adenoids and tonsils calls for genuine skill, and that a nicety of judgment must decide as to whether they should be interfered with or left alone.

MEASLES AND VENTILATION ON BOARD SHIP.

A PAPER on "The Ventilation of Emigrant Ships," by Dr. P. H. Bryce, chief medical officer of the Department of the Interior in Canada, appears in the *Journal of the American Public Health Association* for September. He there tells a story which shows how generalised an infection may become when once it is introduced into a community very closely packed together and without adequate ventilation. An emigrant ship left Rotterdam on June 13th for Canada. At that busy time of year she probably carried passengers nearly to the limit of her statutory capacity. On June 14th, the day after sailing, a child developed measles, and was immediately isolated with the whole of its family, but in the short interval it had done all the mischief it could. In the same compartment with it were 51 families, 279 persons in all, and amongst them the second case appeared on the thirteenth day, June 26th, which was the day of arrival in Canada. Twenty-one more cases were recognised the same day before the ship arrived at quarantine, and another dozen were seen before 9 P.M. that night. In all 71 cases developed, and from that single case Dr. Bryce tells us "every non-immune person [in that compartment] was infected within the short space of twenty-four hours." Fifteen families wholly escaped, but their members were either grown up or protected by previous attacks. The cubic space available for each person was probably the same as in English emigrant ships, 105 cubic feet on a deck 7 feet high, and if we may suppose, as is not unlikely, that this ship was no better

[1] THE LANCET, August 12th, 1911, p. 448.

ventilated than that on which Dr. Bryce crossed when he found 10 to 12 parts of carbonic acid per 10,000 volumes of air, the hourly ventilation supply for each person cannot have been more than 700 cubic feet. Propinquity—that is, small cubic space and close neighbourhood—accounted for the spread of the disease to the nearer children, but the dissemination of the infection to the remote corners of the compartment occurred because the infective particles were not quickly enough carried away in a good flow of air as they should have been, but were left to diffuse themselves everywhere throughout the air of that passenger deck. And we would put it to shipowners—whether it is more expensive to pay for dealing with 71 infectious cases and the isolation for the necessary time of 36 families, or to put satisfactory ventilation on board and so minimise these risks. And by satisfactory ventilation we mean for each adult 1300 cubic feet of properly warmed air per hour suitably introduced into, and removed from, the compartment. The more numerous are the inlets and the outlets the more directly and quickly will the used and, in these cases, infected air be removed, and the smaller chance will there be of the spread of infection.

THE MEDICAL RECORD OF MANCHESTER GRAMMAR SCHOOL.

OUR Manchester correspondent some weeks ago described the work done by Dr. Alfred A. Mumford in reporting a year's record of the health of the boys in considerable detail. Every boy has a medical record card which not only notes the result of medical examination, but also the boy's games, out-of-school occupation, way of travelling to and from school, and a number of other points. We cannot but be struck, as our correspondent was, with the thorough nature of the medical supervision exercised as compared with what is possible in elementary schools, and return to the subject from this point of view. Since 1905 boys from the ordinary elementary schools have been admitted to the Grammar School in considerable numbers. Very interesting, therefore, is Dr. Mumford's careful and accurate comparison both of physical conditions of the boys and social conditions of the parents. The alleged change in social condition is shown by a comparison of two groups of parents of 1285 boys in the period 1881–86 and in 1905–10—that is, since the admission of elementary scholarship boys. The cases chosen are taken consecutively from the school register and are classified according to the parents' occupations :—

Occupation of parents.	1881–86.	1905–10.
Professional	22·2 per cent.	23·5 per cent.
Retail trade	11·0 ,,	11·0 ,,
Higher mercantile	33·0 ,,	25·0 ,,
Lower mercantile	11·0 ,,	21·9 ,,

Higher and lower mercantile indicate positions in business of greater and less responsibility. The rest of the parents belong to smaller groups. A comparison of the physical and health conditions of the boys shows a decided advantage for the period since the beginning of the scholarship system. At age 16 the boys are 1½ in. taller and 8 lb. heavier than a generation ago. Chief among the causes which have led to this result Dr. Mumford puts "the steady diminution ... postponement of early infectious disease in childhood, due to the progressive operation of the Public Health Act of 1875." A second cause is indicated in the changed attitude towards athletics, and other factors are better housing, "increased knowledge and use of foods," and "a greater insight into the meaning of parental responsibility as regards health." With regard to infectious disease, Dr. Mumford traces its ill-effects particularly on vision, and gives a table showing that there is a direct relation between infectious illness in childhood and defective vision later. The value of this excellent report would have been increased had the results of a more detailed comparison between present "free" scholars and the other boys been given. The weight comparison given can only be doubtfully accepted as a test of good physique and well-being.

KALA-AZAR AND THE MOSQUITO.

IN another part of the present issue (p. 1268) will be found an interesting communication by Professor Franchini of Bologna as to the mosquito being the intermediary host and transmitting agent of kala-azar to man. He sets out the details of some experiments carried out by him with the view of demonstrating that in the alimentary tract of anopheles the parasitic organism of the disease can live and multiply; and surmises that as kala-azar is largely found in malarious districts the mosquito is, in all probability, the usual carrier of the infection. Professor Franchini infected his mosquitoes by feeding them on cultures of leishmania, but in his preliminary paper he does not, of course, suggest that this mode of infection could occur in nature. It is fair to point out that Professor Franchini states that further research upon the subject is required, to ascertain, for example, in what part of the mosquito's alimentary tract the leishmaniæ live and undergo multiplication, and to find out if the insect can transfer the infection from one animal to another after being fed on infected blood. These and other problems connected with this most interesting and important subject will no doubt be reported upon by him when he has carried out the further series of experiments referred to by him in his paper. As most readers of THE LANCET are doubtless aware, there are three varieties of the leishmania infection now classed under the general term of leishmaniosis (named after the distinguished discoverer of the protozoal parasitic organism). The first is the kala-azar met with in India, China, and other parts of Asia, in which the infecting parasite is known as leishmania donovani. This is a very fatal form of the disease. The second is known as infantile kala-azar, and is met with along the shores of the Mediterranean Sea and elsewhere, the infecting organism being the leishmania infantum; it is of a more benign nature. Lastly, there is the variety of the malady met with in North Africa, the Near East, India, and in other parts of Asia under the name of oriental sore, Delhi boil, or Bagdad sore, the parasitic cause being leishmania tropica. Professor Franchini does not state which one of the three forms of leishmaniosis is, in his opinion, transmitted by the anopheles, or if all the forms are equally transmissible in this way. Probably it is leishmania infantum, the variety found in Southern Italy, to which he refers. In the introductory part of his paper he adverts to negative results obtained from experiments on the bed bug (cimex lectularius), the dog flea (pulex serraticeps), the human flea (pulex irritans), and the head louse (pediculus capitis), but this position is hardly consistent with the reports of Nicolle, Basile, Pianese, and others who have shown that the dog in Tunis and other parts of the Mediterranean littoral suffers naturally from the same disease which attacks children and which is caused by leishmania infantum, and further that this parasite can be transferred from dog to dog or from dog to man by the dog flea and sometimes by the human flea. Basile, for example, took laboratory bred puppies and allowed infected fleas to feed upon them, with the result that they became infected and died from the disease, the leishmaniæ being found in the bodies of the puppies. Dogs, therefore, may serve as reservoirs of the parasite, and any blood-sucking insect like the mosquito, as suggested by

Professor Franchini, may upon occasion transmit the disease from the dog to man. Nicolle believes that the dog- and the human-fleas are the common transmitting agents of leishmania infantum. In India it has so far been found impossible to infect dogs or any other animal with leishmania donovani. Rogers, Patton, and others regard the Indian bed bug, cimex rotundatus, as, in all probability, the usual carrier of kala-azar to man, though occasionally the conorrhinus subfasciatus, a plant-feeding bug generally, but which at times becomes a blood-sucker, may act as the transmitting agent. As regards the leishmania tropica, Dr. R. Row has recently in India brought forward evidence in support of the view that the domestic fly is the actual carrier of this parasite to man. There is nothing improbable in the idea that leishmania in any of its three forms may be spread by one or another kind of biting insects—ticks, lice, bugs, fleas, mosquitoes, or even by flies—but, except as regards the bug in India and the flea in North Africa and the Mediterranean littoral, there has been no direct evidence brought forward to inculpate other biting insects. Professor Franchini's paper opens up a new field of investigation, and we hope to have from him before long further information as to his incrimination of the anopheles. For those who are interested in the subject we refer them to a critical review of Kala-Azar and Tropical Sore by Colonel Sir W. B. Leishman, F.R.S., R.A.M.C., published in the *Quarterly Journal of Medicine*, Vol. V., No. 17, October, 1911.

GONORRHŒAL PERIOSTITIS OF THE LONG BONES.

GONORRHŒAL affections of bone are much less common than gonorrhœal affections of joints. The epiphyses and small bones of the hands and feet are the most frequently affected. Periostitis of the diaphyses is so uncommon that it is unmentioned in most text-books, and its existence has been disputed. In the *Journal of the American Medical Association* of August 19th Professor Stephen H. Watts has reported the following case. A man, aged 24 years, was admitted to the Johns Hopkins Hospital on Jan. 2nd, 1907, complaining of an abscess in the left thigh. His illness began with gonorrhœa four weeks before. Two weeks later a swelling appeared in the left thigh and became painful, hot, and hard. As he could not use the leg he remained in bed for a week before admission and the discharge ceased. He lost appetite, was constipated, and had night sweats. A bubo appeared on the left side, but disappeared without discharging. On examination he was healthy-looking; the temperature was 103·6° F., and the pulse 90 and of good volume. The leucocytes numbered 12,400. There was purulent balanitis, and the pus contained gonococci. On the anterior and outer aspects of the middle third of the left femur was a tender indurated area 10 by 14 centimetres, apparently an abscess beneath the quadriceps. The skin was hot but not reddened. The hip and knee-joints were normal. An incision 14 centimetres long was made over the swelling. The muscles were separated, and the swelling was found to be due to a small collection of turbid but not purulent fluid beneath the periosteum. It contained the gonococcus in pure culture. The periosteum was very thick, œdematous, and lined by velvety granulation tissue. The exposed bone was slightly roughened by deposits of new osseous tissue. The wound was irrigated with mercury bichloride and packed with iodoform gauze. Sections of the thickened periosteum were examined by Dr. W. G. MacCallum who reported: "The section shows some new-formed bone embedded in a great deal of very vascular granulation tissue. Outside of this there is muscle, the individual fibres of which are separated by the same granulation tissue. No definite organisms can be seen." After the operation the temperature ranged up to 102° and there was a small amount of purulent discharge. The whole of the thigh was swollen and the femur seemed to be thickened and tender. A skiagram showed deposits of new bone about it. The patient improved and the thigh became less swollen, but the bone seemed thicker than ever. In the middle of February the wound healed and he could walk, but the femur remained greatly thickened. He was discharged. He was seen again in August, when his general condition was good, but there were great thickening of the femur and a small sinus in the middle of the scar. He was then lost sight of. Gonorrhœal affections of the periosteum were first described in 1869 by Fournier. He distinguished periostitis and periostosis, the former being simple inflammatory deposits in the periosteum, the latter being tumours resulting from infiltration between the bone and periosteum. He insisted on the much greater frequency of periostitis, which produces slight circumscribed ephemeral swellings most frequently on the tibia just above the insertion of the sartorius, on the lower end of the humerus, on the upper end of the fibula, on the great trochanter, on the posterior surface of the os magnum, and on the extremities of the metacarpal and metatarsal bones. The only symptoms are pain in a circumscribed area, with perhaps a little œdema and tenderness of the overlying skin. Gonorrhœal periostitis is frequently associated with gonorrhœal arthritis.

THE RISKS OF INTRAVENOUS INJECTION OF SALVARSAN.

AT a meeting of the Académie de Médecine of Paris on Oct. 10th M. Hallopeau reported a case in which death followed the intravenous injection of salvarsan by a practitioner who rigidly followed the rules laid down for its administration. The patient was a robust, well-developed man, aged 35 years, who contracted syphilis in 1902. He had been addicted to alcohol, but had abandoned the habit for two years. He had in succession a chancre, roseola, mucous patches, and a relapsing palmar and plantar psoriasiform eruption. He was treated at first with mercury and then with 10-centigramme injections of hectine without effect on the eruption—a result probably due to the fact that the dose was too small. In July, 1911, three months after the last injection, he demanded treatment by salvarsan. An intravenous injection of 30 centigrammes was given and was well borne. On the sixth day an injection of 40 centigrammes was given. After a few minutes he was seized with a sensation of dryness in the throat, accompanied by congestion of the face and anguish. These symptoms lasted some minutes. He was able to take a walk in the afternoon without any feeling of malaise. In the night he suffered from nausea, which was followed by vomiting. On the following night the same symptoms recurred, and on the next day he was seized with anguish and convulsions. The temperature rose to 101·3° F. The pulse was normal and strong. Several attacks of convulsions with chewing movements followed; the eyes were turned upwards and to the left. There were congestion of the face, tremor of the upper limbs, and clonic and tonic spasms, and the temperature rose to 104°. In the night he gradually became comatose and died in an attack of convulsions. The short interval between the second injection and the appearance of the symptoms suggested that they must have been due to the salvarsan, but the reason for their occurrence was not evident. The patient showed no signs of visceral disease. It might be suspected that his previous alcoholic habits had caused some change in his liver, but of this there was no indication. Similar cases have been recorded by other observers, and others have

occurred which have not been published. In a case recorded by B. Fischer, slight changes were found in the liver at the necropsy, indicating former alcoholism. M. Hallopeau concludes that salvarsan should not be given to persons who have been addicted to alcohol, even though they have abandoned the habit for some time. He went, as a matter of fact, much further and suggested that a drug which in ordinary doses might prove fatal to persons in no danger should have no place in routine therapeutics. In the discussion which followed he was supported by Professor Gaucher, who declared that he knew similar cases. He insisted that salvarsan does not cure syphilis but only certain manifestations of it, particularly ulcerative lesions, and does not prevent relapses which are almost constant. He passed his time, in hospital and private practice, in seeing patients on whom salvarsan produced no, or only a temporary, effect, and believed that patients thought themselves cured by it, and after one or several injections were lulled into a false sense of security. If they then followed no other treatment they were exposed to worse consequences.

THE ROYAL INSTITUTE OF PUBLIC HEALTH: BERLIN CONGRESS, 1912.

THE Council of the Royal Institute of Public Health has accepted an invitation from the Lord Mayor of Berlin to hold its Congress in 1912 in that city, from Thursday, July 25th, to Sunday, July 28th, inclusive, and a local general arrangements committee has been formed, consisting of representatives of the Royal Ministry of the Interior, the Imperial Board of Health, the City of Berlin, the medical officers of the Headquarter Staffs of the Army and Navy, the University of Berlin, the medical and hygienic societies of Berlin, &c., to promote the success of the meeting. The Congress will be under the Presidency of Earl Beauchamp, His Majesty's First Commissioner of Works, and will be conducted in the following sections:—A, State Medicine (President, Sir T. Clifford Allbutt); B, Bacteriology and Comparative Pathology (President, Professor G. Sims Woodhead); C, Child Study and School Hygiene (President, Sir James Crichton-Browne); D, Military, Colonial, and Naval (President, Sir Ronald Ross); and E, Municipal Engineering, Architecture, and Town Planning (President, Mr. P. C. Cowan, Chief Engineer of the Local Government Board, Ireland). The various Congress and sectional officers will also include distinguished scientific and municipal persons of German nationality. Facilities will be afforded for visiting the various public health and educational institutions in Berlin, and the opportunities thus given to representatives of municipalities, county councils, and other sanitary authorities of the United Kingdom for becoming practically acquainted with institutions in the work of which they are concerned should be of the greatest value. Mr. James Cantlie, honorary secretary of the Institute, informs us that arrangements are being made for travelling and hotel accommodation at reduced charges, the subscription for each delegate being one guinea.

THE King has given to the undermentioned gentlemen His Majesty's authority to accept and wear the decoration of the First Class, Third Division, Imperial Chinese Order of the Double Dragon, which has been conferred upon them by His Majesty the Emperor of China, in recognition of valuable services rendered by them during the recent epidemic of pneumonic plague—namely, Mr. William Harold Graham Aspland, M.D. Toronto, F.R.C.S. Edin., medical professor at the Union Medical College, Peking; Mr. John Maitland Stenhouse, M.B., B.C. Cantab., of the Union Medical College, Peking; and Mr. Bernard Score Browne, M.B., Ch.B. Edin., of the Church Missionary Society Hospital, Ningpo.

THE annual dinner of the Harveian Society of London will be held at the Café Royal, Regent-street, on Thursday, Nov. 9th, at 7 for 7.30, when the chair will be taken by Mr. Ernest Lane, the President.

THE First International Eugenic Congress will be held at the University of London from July 24th till 30th, 1912, under the presidency of Major Leonard Darwin, who will be supported by a number of vice-presidents of international reputation. These include the Lord Chief Justice of England, the Presidents of the Royal College of Physicians of London and of the Royal College of Surgeons of England, the Principal and Vice-Chancellor of the University of London, and representatives of the United States and of the great European countries. The papers will be grouped into four sections: (1) The bearing upon eugenics of biological research; (2) the bearing upon eugenics of sociological and historical research; (3) the bearing upon eugenics of legislation and social customs; and (4) the consideration of the practical applications of eugenic principles. The Congress will be organised by the Eugenics Education Society, and all communications should be addressed to the honorary secretary, 6, York-buildings, Adelphi, London.

MOTORING NOTES.

By C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The Olympia Motor Show.

THE Tenth Annual Exhibition of Motor-cars organised by the Society of Motor Manufacturers and Traders is now open, and the medical man in search of a motor will find many from which to select. For our well-to-do colleagues there are the cars costing many hundreds of pounds, and alongside others priced at but a tenth part of such a sum. As a result of a careful walk round on "press" day I was convinced that the man must be hard to please who cannot find some car among the many shown which will meet with his approval.

The general arrangement of exhibits follows the plan proved to be satisfactory in the past, but a slight alteration has permitted bringing together in one group the individual displays of the body-builders. Entering the hall from Addison-road, chassis and cars will be found at the eastern and central portions of the ground floor. At the western end the body-building firms maintain the traditional reputation long ago secured by British carriage-builders. The popular torpedo flush-sided bodies, landaulettes, limousines, and cabrio-landaulettes are all shown in a remarkable variety of forms, and among many attractive designs, which are bound to draw attention, are the productions of Messrs. Mulliner, Morgan and Co., Messrs. Vincent of Reading, Messrs. Hora of Peckham, The Connaught Motor and Carriage Co., Limited, Messrs. Brown, Hughes, and Strachan, Messrs. Maythorn, Messrs. W. and F. Thorn, and Messrs. Alford and Alder. Adjoining the Hammersmith-road entrance, and immediately opposite, on the northern side of the hall, are electric lifts which convey visitors to the galleries, where a whole day can be spent amidst a multitudinous array of engines, parts, and accessories. The south gallery is devoted to exhibits of tyres, detachable wheels, and rims.

A good many medical friends have questioned me as to the best car. I feel inclined to reply, like the critic did in *Fanny's First Play*, when requested by the father to give an opinion on his daughter's work: "Tell me who it is by and I will tell the sort of play it is." So in the case of cars, the makers' names help in arriving at a conclusion. The following, among others, should certainly be looked at by the doctor visiting Olympia with a view to the purchase of a new motor: The Adler,

which in addition to its excellent design has body-work by Messrs. Morgan; the Albruna, shown by Messrs. Brown Brothers, of Great Eastern-street, London, E.C., the smaller one of which seemed to me to be an ideal two-seater; the Argyll, an old favourite with the profession, and now fitted with a sleeve-valve engine, with combined reciprocating and partial rotary motions, and regarding which I hope to give a detailed account on another occasion; the Arrol Johnson, the Austin, the Belsize, the two- and four-cylinder Briton; the Charron, sold by the London Motor Garage Co., Limited, of Wardour-street, who issue inclusive maintenance contracts covering every expense connected with the car; the Daimler with the Silent Knight engine, which was described in THE LANCET of April 15th, 1911; the Darracq, of which cheap and trustworthy car five types are shown. the 11-h p. costing complete with a two-seater body but £195. Their other types have a worm drive, and one model has a cylindrical distributer which does away with valves, spring tappets, and cam shaft. The De Dion, as always, are well to the fore with their 6 h.p. single, and 7 and 9 h.p. two-cylinder cars. Messrs. Humber have a 5½ h.p. air cooled two-cylinder two-seater, which costs but £95; and they also show 11, 14, and 12-20 h p. cars. Other excellent cars are the 17 h.p. Maudslay, the American Mitchell, the Napier, the Panhard, the 6 h.p. Pilot, the various Renault models, especially their little two-cylinder 8 h.p. and four-cylinder 12 h.p., the satisfactory Rovers, including the old and popular 6 h.p. poppet valve, and the newer 12 h.p. two-cylinder Silent Knight. the Star, Straker Squire, Swift, Talbot, Vauxhall, and Wolseley. All these cars are the work of old-established makers, and any one of them has a name which is a guarantee of good workmanship. The single- and two-cylinder cars certainly maintain their previous popularity, and this type has many points for the medical man who merely desires a car for professional use, which he can look after and drive himself. In external appearance engines now approach towards an oblong block, with valve stems and springs enclosed. The poppet valve, I am glad to note, is still popular, though there are many devotees to the sleeve and rotary type. The efficiency of an 80 mm. bore has directed the designer's attention to smaller sizes, and many chassis are shown carrying engines to be known as 11·9, smaller editions of the popular 15·9. Undoubtedly the smaller one is fitted for a two-seater, but I do not think it should be expected to carry heavy four-seated bodies. Lubrication devices have certainly improved, and to-day the motorist replenishes his oil tank less frequently than his petrol container, and if too much or too little be given simple tell-tale signals instantly inform him of the fact.

Automatic carburetters are also general, and the fuel consumption is probably now at a minimum. The leather-faced clutch still holds its own against the multiple disc, and this is to be welcomed, especially as the leather is attached in sections and can be easily replaced when worn. Declutching is no longer laborious, thanks to lighter springs and compound leverage. The demand for greater flexibility of control has introduced more four-speed gear-boxes, which enable a better average speed to be maintained in hilly districts. On nearly all the cars the final transmission is by a propeller shaft and bevel or worm drive. In the worm drive many place the driving worm above the driven worm wheel; this may not be as easily lubricated as when the driving worm is below, but it gives greater road clearance and saves wear on the universal joints of the cardan shaft, keeping the propeller shaft more horizontal.

Comfort for passengers on cheap as well as expensive cars, in the matter of a well-sprung chassis, hardly admits of further improvement, but the addition of such devices as shock absorbers makes cars so fitted travel with luxurious smoothness. Moreover, the tyres are always in contact with the road surface, and thus their life is prolonged. Tyres are, of course, of the first interest to the motorist, and the Dunlop, Continental, Michelin, Spencer-Moulton, and Stepney road grip, in addition to being as good as ever, have this advantage—they are much cheaper. Of lamps, many are shown, and for medical men I must confess I like the electric, such as shown by Messrs. Longstreth's, C. A. Vandervell and Co., and Brown Brothers. Messrs. Vandervell's dynamo to be driven off the motor seemed light, neat, and simple.

Thomson Bennett show a useful exhaust car-heater, in which the heat could be regulated, and which would be ideal for work in winter. Harvey Frost show their vulcanisers, which are useful for prolonging the life of inner tubes and covers. For tubes, too, "Quick Patch" patches are of value.

PLAGUE AND FEVER PREVENTION IN INDIA.

MOST people know that during the last 10 or 15 years India has been visited by severe outbreaks of plague and malarial fever that have caused an enormous loss of life. This has probably been far less than had been the case in old-time epidemics before statistics were published or even thought of. Nevertheless, the continued prevalence of plague in many parts of the country, and the recurrence of malarial outbreaks of great severity, had naturally caused some anxiety. Opportunity was taken in September, in reply to a question at the Imperial Legislative Council at Simla, to give a succinct account of what has actually been done, and is now in course of being carried out by the responsible authorities to safeguard the health of the country.

Statistics.

It has often been said that sanitation is based on statistics, it being implied that the statistics are trustworthy. As far as a great part of India is concerned it has to be admitted that the registered causes of death are very misleading. It is therefore not possible to indicate accurately the direct effects of malaria and plague prevalence on the growth of the population. Nevertheless, the provisional figures of the 1911 census, which show an actual reduction in the populations of the United Provinces and of the Punjab since 1901, are evidence of the terrible severity of the visitations of these two diseases. Plague chiefly shows itself in greatly increased mortality; epidemic malaria, besides this, causes a great diminution in the births during the year following the outbreak. The United Provinces, where there had been famine in 1905–08, in this latter year were devastated by the most severe epidemic of malaria that had ever been known; during the decade (1901–10) more than a million and a half people died from fever *in excess* of those who had died from this cause in the preceding decade. In the same period the plague deaths numbered over 1,300,000. The Punjab also suffered severely, the deaths from plague and malaria during the ten years 1901–10 having been more than a million and three-quarters in excess of those due to these two diseases in 1891–1900.

Work and Discoveries in India.

The Sanitary Commissioner calls to mind the fact that almost the whole of the knowledge on which efficient and precise measures against fever and plague are based is the result of action taken and discoveries made in India. With regard to the former disease the extensive development of cinchona plantations has been the chief means of bringing about such a fall in the price of quinine as to make it available for the poorest peasants; the Indian Government also started the plan of selling doses of quinine for the smallest coin current in the country (pice packets). Again, the discovery of the mode of spread of malaria was the work of an Indian medical officer, Sir Ronald Ross; it is entirely owing to this discovery that precise and rational preventive measures have been made possible. As regards plague, the discovery and provision of preventive inoculation, the recognition of the part played by rats in the epidemiology of the disease and of the mode of infection and conveyance by the rat-flea have placed preventive measures on a rational basis.

Preventive Measures.

In 1909 a conference was held at Simla to consider the question of malaria in all its bearings; a permanent organisation to deal with the matter was established, consisting of a central scientific committee, provincial committees, and a general committee, consisting of the central body combined with delegates from the various provincial committees. It was decided that the first requirement was a knowledge of all the circumstances connected with the disease as it presented itself in different localities. As a result, in the early

part of last year, a Malaria Bureau was established at Kasauli, near Simla; and at Amritsar, in the Punjab, a permanent laboratory was established, where classes of instruction for medical officers and subordinates have been held, under Major S. R. Christophers, I.M.S. These specially trained experts have been distributed throughout the different provinces, their work being entirely devoted to the investigation of malaria and its prevention.

In Madras an officer has been specially deputed to inquire into the causes of variation in intensity of malarial prevalence in Jeypore (Vizagapatam); much anti-malarial work on the usual lines has been carried out in different directions; and a Malaria Board and special malaria officer are to be appointed. In Bombay a provincial committee has already been formed for this purpose. Dr. C. A. Bentley has carried out an exhaustive investigation as regards the city of Bombay, his final report having just been published [1]; and many individual investigations have been made in selected districts. In Bengal a specially trained officer has been appointed, with a staff of assistants, for research work; draining has been carried out in several towns, and quinine freely distributed. In the United Provinces two medical officers have been appointed for research; a provincial and eight divisional committees are at work making inquiries, educating the people, and popularising the use of quinine; in four specially selected districts travelling dispensaries have toured from village to village giving medical relief.

In the Punjab, in addition to the establishment of a provincial committee and chief malarial officer, Major Christophers was specially employed in 1909 to investigate the very severe epidemic prevalence. His report has just been published, showing that periodical flooding has been an important factor, and that preventive measures are quite practicable. In Eastern Bengal and Assam Major Christophers and Dr. Bentley inquired into the incidence of blackwater fever; their report of 1908 settled many vexed questions regarding its etiology. Their recommendations have been carried out by a large number of planters in the province, and great improvement in regard both to blackwater fever and malaria has already resulted. Consequent on a second report by the same officers on malaria in the Duars in 1909, a committee has been appointed to inquire into the sanitary and economic conditions of the tea-garden coolies. In the Central Provinces and in Burma committees and special investigation officers have also been appointed.

Similar action, *mutatis mutandis*, has been taken with regard to plague prevention. A yearly grant of 30 lakhs of rupees (about £200,000) has been devoted to the improvement of sanitation, with special reference to plague. In the present financial year an additional special grant of 57 lakhs has been made for expenditure chiefly on drainage schemes likely to improve malarial conditions in towns.

This brief recital of the more important, though not by any means of the whole, of the measures adopted by the Government of India in regard to disease prevention will show that the Imperial authorities are fully alive to the importance of preserving the health of the community, and are grappling with the inevitable difficulties in a scientific and statesmanlike fashion. In such a vast area, with such widely differing local conditions, there can be no sudden cessation of epidemic disease from Cape Comorin to the Himalaya; but improvement has already been very perceptible, and we feel assured that it will be progressive.

[1] THE LANCET, Oct. 28th, 1911, p. 1221.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual meeting of Fellows and Members will be held at the College, Lincoln's Inn-fields, on Thursday, Nov. 16th, at 3 o'clock P.M., when the report of the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the secretary, and can, if they so desire, have their names placed on the list of those to whom the report is sent annually. Motions to be brought forward at the meeting must be signed by the mover, or by the mover and other Fellows and Members, and must be received by the secretary not later than Nov. 6th. A printed copy of the agenda will be issued to any Fellow or Member who may apply for one on or after Nov. 13th.

THE LONDON COUNTY COUNCIL AND THE DENTAL TREATMENT OF SCHOOL CHILDREN.

A REPORT was presented to the Education Committee of the London County Council on Nov. 1st with regard to the results obtained in the experimental schemes for the dental treatment of school children begun during the year in four districts of London. Agreements were entered into with the Poplar Hospital for Accidents, the St. George's Dispensary, Blackfriars, the Deptford Health Centre, and the Wandsworth Medical Treatment Centre.

The Progress of the Local Experiments.

The report stated that with regard to the Deptford and Poplar experiments, while the Council realised that the most appropriate age-group from a purely dental point of view was from six to eight years of age, the period of eight to nine was selected because the ordinary medical inspections included the examination of children of this age, and because it was known that a considerable amount of dental caries existed among those children, for which it would be necessary to provide facilities for treatment. In both cases it was found at an early stage to be necessary to supplement the work of the school medical officers by special dental inspections, and the Council sanctioned the reduction of the time allotted to treatment from ten to nine sessions a week, and authorised the employment of the dentist on the remaining session for the dental inspection of children attending schools in the areas served by the respective centres. The Council, on March 7th, 1911, and on July 4th, 1911, approved two further experiments—viz., (1) at St. George's Dispensary, Blackfriars, and (2) at the Wandsworth Medical Treatment Centre. As special dental inspections had become necessary, the reason for the selection of the older age-group was removed, and the Council, in these two experiments, provided for the treatment of children between six and eight years of age, and for the treatment, in special cases, of children of other ages. Arrangements were made for the dentist in each case to be employed on one session a week to conduct dental inspection in the schools and to select cases for treatment. From the outset it was recognised that difficulty would be experienced in obtaining the consent of the parents, owing to the fact that, in the absence of actual suffering, the need for treatment was not generally appreciated. With a view, therefore, of educating parents in dental hygiene the Council sanctioned lectures by Mr. C. E. Wallis in the vicinity of the centres, and leaflets and cards on the care of the teeth had been circulated. The experimental period at Deptford and at St. George's Dispensary would expire on Dec. 31st, 1911, and it was necessary to decide whether the arrangement should be continued. The consent of the Board of Education in both cases was given on the understanding that, in the event of any application for renewal, the Board would be supplied with reports upon the working of the schemes in sufficient time for consideration before the end of the experimental period.

The Results Obtained.

At the Deptford centre the agreement provided for the treatment of 3960 cases per annum. During the 29 working weeks ended Sept. 30th, 1911, 1594 children were treated, or at the rate of 2420 a year. In addition to 2563 extractions and 2690 fillings some 300 minor operations, such as medical dressings in teeth, scaling, and cleansing had been performed. Of fillings performed 2481 were permanent teeth and 209 temporary; and of extractions 364 were permanent teeth and 2199 temporary. With regard to the discrepancy between the number treated and the number provided for, it should be pointed out that the deficiency was much more serious at the beginning of the scheme than at the present time—e.g., out of a possible 180 appointments during the fortnight ended Jan. 21st, 1911, 49 appointments were kept, while during the fortnight ended Oct. 21st, 1911, 138 children attended the centre. The dentist reported that considerable advantage had resulted from the inspections conducted by him in the schools, inasmuch as they had afforded him an opportunity of arousing the interest of the teachers and children in the work. The experiment at St. George's Dispensary was put into operation in May, 1911. The agreement provided for

the treatment of six cases a session (approximately 1300 a year), but whenever possible endeavour had been made to secure the attendance of eight new cases a session (approximately 1760 a year). During the 16 working weeks ended Sept. 30th, 1911, 457 children attended the centre, or at the rate of 1250 a year. There could be no doubt that dental caries was sufficiently prevalent to justify all the provision for treatment made in the districts served by these two centres, which, notwithstanding the difficulties incidental to the inauguration of new schemes of this nature, had done good work.

In view of the impending reorganisation of the Council's medical work, the committee did not propose to deal with the general question of the dental treatment of children, but the two centres were quite suitable for retention as part of a permanent scheme, and the local committees were prepared to continue the work. All the dentists concerned were in agreement that an anæsthetic was essential in difficult cases of extraction, but no provision had been made for dealing with these cases, and it had been necessary at all the centres to withhold treatment. The Council, however, on August 1st, 1911, sanctioned the employment of an anæsthetist in connexion with the treatment at the Poplar Hospital, and it was proposed that this provision should be extended to all the schemes. On the question of age, it was proposed to provide for the treatment of children from six to eight years of age, selected as the result of special dental inspections, and also, for the present, for the treatment of children of eight to nine years of age selected by the school medical officers, and of any specially urgent cases which might arise. The basis of payment by the Council was £50 a year for one half-day's service a week of the dentist or anæsthetist, and 2*s*. per case treated.

The cost involved in the two schemes was therefore as follows:—Deptford Centre: Salary of dentist (seven half-days a week), £350; salary of inspecting dentist (one half-day a week), £50; anæsthetist (one half-day a week), £50; capitation grant on 3080 cases, £308; total, £758. St. George's Dispensary: Salary of dentist (five half-days a week), £250; salary of inspecting dentist (one half-day a fortnight), £25; anæsthetist (one half-day a fortnight), £25; capitation grant on 1760 cases, £176; total, £476. The sub-committee recommended that, subject to the approval of the Board of Education, the agreements with the Deptford Health Centre and the St. George's Dispensary, Blackfriars, be renewed as yearly agreements as from January, 1912.

The proposal was approved and the report was forwarded to the Council.

THE TECHNICS OF PLUMBING.—A meeting to inaugurate a course of special lectures on sanitary plumbing was held on Oct. 18th at the London County Council Schools, Ferndale-road, Brixton. The lectures are instituted by the Council for the National Registration of Plumbers under the auspices of the Worshipful Company of Plumbers and the London County Council. Mr. W. D. Caroë, M.A., F.S.A., architect to the Ecclesiastical Commissioners and Past Master of the Plumbers' Company, took the chair, in the absence of the present Master, the Lord Mayor. The meeting was well attended. Mr. Caroë having read a letter from the Lord Mayor regretting his inability to be present, said that he considered the lectures, being given by practical men well versed in all the technicalities of the trade, should inspire confidence in those attending them, and promised to move the court of the Plumbers' Company to offer some award to the successful students. Mr. Fretwell, teacher of sanitary plumbing, then delivered a lecture on Domestic Water-supply. The lecturer described the various forms of boilers and methods of circulating hot water by cylinder, tank, and auxiliary systems. Diagrams were shown, and the relative cost of heating water by coal and coke fires and electricity was gone into. In conclusion, Mr. Caroë congratulated Mr. Fretwell on the lucidity of his lecture, which he (Mr. Caroë) would like to see in print. The usual vote of thanks followed. After the lecture specimens of the standardisation mark applicable to plumbers' work under the regulations of the Board of Trade were shown on pipes of lead, cast and wrought iron, and copper, and the system of marking was explained by the clerk of the Plumbers' Company, Mr. W. R. E. Coles.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH FOR 1910.

City of Liverpool.—Dr. E. Hope's annual volumes form one of the most instructive records of municipal sanitary progress which we possess, and his last report, like its predecessors, is a model in form, arrangement, and illustration. The population of Liverpool is estimated for 1910 at 743,295. The Registrar-General's estimate, based on the 1901 and previous Census returns, approximated closely to the figures obtained by actual enumeration in 1911, and in this respect Liverpool contrasted markedly with Glasgow, Edinburgh, Birmingham, Leeds, and other large cities where the numbers proved to be considerably below anticipations. The usual thinning of the population of the central parts of a great city is, however, seen in Liverpool as elsewhere; during the last ten years the increase has been towards the city boundaries, especially in Walton, West Derby East, and Wavertree. The high birth-rate of Liverpool was maintained in 1910, being 31 per 1000, against 24·8 for England and Wales; the death-rate has declined to 17·9 per 1000, the lowest so far recorded, representing a reduction of 25 per cent. in 15 years. The report gives particulars of the progress made in dealing with insanitary dwellings and houses unfit for human habitation, and has interesting sections on the result of the continuous efforts made in Liverpool to improve the food- and milk-supply. On the latter question Dr. Hope gives further facts which prove that the cowsheds and cows within the city are in a more satisfactory condition than those in the country whence milk is dispatched to Liverpool. In regard to tuberculosis, four samples out of 289 milks of "town" origin proved infective on guinea-pig inoculation, against 15 out of 323 country samples. Dr. Hope draws attention to the enormous reduction in the mortality of scarlet fever which has been effected during the past 30 years, and inquires whether similar reduction may not be practicable in the case of measles and whooping-cough. There is no doubt that much of the spread of the latter disease, particularly in tenements, could be obviated by hospital isolation, but the fact that so huge a proportion of those attacked are infants who would need to be accompanied by their mothers presents a considerable difficulty. Isolation for a limited number of cases, both of measles and whooping-cough, has, however, been provided in the city hospitals. In dealing with tuberculosis Dr. Hope insists on the association of the disease, all through the history of Liverpool, with the construction of its mean streets and alleys and the thousands of insanitary courts and cellar dwellings, which at one time housed as many as 120,000 people. In connexion with the clearance of certain insanitary areas by the corporation, some 2400 appropriately constructed dwellings have been erected which are let exclusively to former tenants of the areas demolished or to tenants displaced by the corporation from equally insanitary dwellings in the vicinity.[1] In contrast to what frequently obtains elsewhere, in these cases at least 80 per cent. of the occupants were previously the occupants of the former insanitary areas, most of them in extreme conditions of poverty and dependent upon precarious labour for a living. At the time these areas were condemned evidence was available to show that for many years there had been a remarkable incidence of phthisis amongst these people, the average annual death-rate approximating to 4 per 1000. The rate amongst these same people in their new surroundings has fallen during the last two years to 1·9 per 1000, the most material difference being the change of dwelling, together with such alterations in their social habits as have ensued from the change. Hospital accommodation for phthisis cases is at present provided out of funds derived from rates by four independent public authorities in Liverpool. Twenty-five years ago the same observation was applicable to all forms of infectious disease, many of which were dealt with under the Poor-law, and Dr. Hope considers that the time may be approaching for a further advance in dealing with tuberculosis by transfer to the public health authority of such responsibilities connected with the disease, apart from the destitution resulting from it, as are at present

[1] THE LANCET June 18th (p. 1718), and July 2nd (p. 60), 1910.

accepted by the Poor-law authorities. The latter authorities in Liverpool have in recent years spent large sums in erecting hospitals, admirable of their kind, for the accommodation of chronic consumptive patients, and now accommodate some 600 patients either in these special hospitals or in the general Poor-law infirmaries. The public health authority has not at present more than 60 beds available for phthisis. It remains to be seen whether the introduction of an entirely new authority, the Health Committee of the National Insurance Bill, will merely augment the existing administrative confusion to which Dr. Hope refers or can usefully adapt the existing machinery. The voluntary system of notification of phthisis has worked more efficiently in Liverpool than in many other towns. Dr. Hope considers that at present practically all cases are notified in which the public health authority can be of service, and that whether all cases of phthisis should be scheduled for notification is really a matter for the medical profession to determine, and largely on the grounds of its own convenience. The report contains an instructive analysis of the reports on cases of phthisis made by Dr. W. L. Hawksley and the sanitary inspectors specially engaged in home visiting. The school children notified during the year to be suffering from pulmonary tuberculosis numbered 344, and attended as many as 110 elementary public schools. There appears to be no evidence of special incidence on any one school, although generally those in the old city area have a relatively greater number of cases. The future history of these cases, if it can be obtained for a sufficient number of years, should be of much value in determining the significance and prognosis of pulmonary tuberculosis reported at school ages. Out of 23,054 births in the city during the year, 17,257 were attended by midwives. One registered midwife attended over 500 cases, while 90 attended less than 50 cases. The average was 70 cases to each midwife in practice. Medical assistance was required by midwives in 1015 cases during the year. The health committee continues to be responsible for a fee of a guinea for every case of emergency attendance by a medical practitioner at the request of a midwife, provided that the fee cannot be obtained from the patient's friends or the board of guardians. Dr. Hope states that the arrangement has given general satisfaction; the total amount paid by the health committee in 1910 was £464. For ophthalmia neonatorum advantage is taken of the provision of a small ward at St. Paul's Hospital, where infants only a few days old can be received with their mothers, and private generosity has enabled a hospital-trained nurse to be appointed to visit the homes of those patients whose parents are unable to provide adequate attention. It is somewhat surprising that so little favour is shown to cremation in Liverpool. A properly equipped crematorium was provided in 1896 at Anfield cemetery, and its administration was taken over by the corporation in 1908. Only 501 cremations have taken place since 1896, the number in 1907 being 37, if anything a little below the average.

City of Cork.—This city, according to Mr. Denis D. Donovan, possesses the unenviable notoriety of having the highest consumption death-rate of any town in Great Britain and Ireland. There were 233 deaths from phthisis in 1910, a rate of 3·06 per 1000. Mr. Donovan renews his advice that cases of the disease should be made compulsorily notifiable, the voluntary system having resulted in producing no more than 38 notifications in 1910. It is obvious that the prevalence of tuberculosis in Cork is closely dependent on the housing conditions of the population. Out of a total of 12,480 houses some 1300 are without backyards, and some 1800 are tenement houses. The latter contain about 23,000 occupants, approximately a third of the population. Many of them are old and decayed, and some hopelessly dilapidated. Mr. Donovan considers that a very large number of these dwellings are so structurally bad and so dirty that any form of patching or mending them would be useless. On the other hand, he regards their demolition as hopeless until new accommodation is available for those displaced. In this matter he strongly advises the corporation to undertake a large construction of cottages on the outskirts of the town—a practice already begun with satisfactory results—in place of any efforts to house the people on the spot in new tenement dwellings. Mr. Donovan draws attention to the recent construction of 21 private slaughter-houses outside the borough boundary, where considerably more animals are now slaughtered than in the city slaughter-houses, where strict inspection takes place. He advocates also provision of a public abattoir with general closure of the private establishments in the locality.

Ross and Cromarty.—Dr. William Bruce's report on this county embodies some interesting observations on public health matters in the island of Lewis made by Dr. D. Murray, the district medical officer of health. The directions in which improvement is required are now fairly well known, but it is only practicable to press for alterations in the habits of the people with any prospect of success if they first realise the reason of the changes they are asked to make. On this view Dr. Murray has made a special point of supplementing his inspections of schools in the island by evening lectures in Gaelic to parents on the Prevention of Consumption and the Care of School Children, and finds his advice taken in good part and with evident gratitude. The tweed-making industry has grown rapidly in recent years, and in some districts nearly every woman is employed. This necessitates almost constant work inside the house, often until the small hours of the morning. There is reason to fear that the health of the women will by-and-by show deterioration owing to the curtailment of work in the open-air. Infections such as those of measles and whooping-cough are frequently introduced from one village to another by special gatherings, particularly local communions, and Dr. Murray pleads for a recognised rule against any person from an "infected district" attending services outside his area without medical sanction. Typhus fever still occasionally shows itself in the island; nine members of a family in a house in Balallan were affected during the year. A curious prevalence of enteric fever, strongly suggesting the operation of a carrier, has occurred in the remote parish of Uig during the last five years.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7449 births and 4128 deaths were registered during the week ending Oct. 28th. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 14·4 in the nine preceding weeks, further declined to 13·3 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 14·5 per 1000, and was equal to that recorded in London during the same period. The death-rates in the 77 towns last week ranged from 4·5 in Handsworth (Staffs.) and in King's Norton, 6·8 in Hastings, and 7·5 in Northampton, to 18·7 in Wigan and in Oldham, 18·9 in Hull, and 21·3 in Middlesbrough. The 4128 deaths from all causes in the 77 towns were no fewer than 322 less than the number returned in the previous week, and included 334 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 406 in the nine preceding weeks. Of these 334 deaths, 164 resulted from infantile diarrhœa, 48 from measles, 46 from diphtheria, 30 from whooping-cough, 28 from enteric fever, and 18 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 1·1 per 1000, against 1·7 and 1·3 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœa, which had steadily decreased from 2714 to 223 in the nine preceding weeks, further declined to 164 last week, and caused the highest annual death-rates of 1·7 in Rhondda, 2·0 in Burnley, 2·7 in St. Helens, and 4·1 in Wigan. The deaths referred to measles, which had increased from 19 to 37 in the four preceding weeks, further rose last week to 48; the highest annual death-rates from this disease were 1·3 in Norwich, 2·4 in Burnley, and 3·3 in Wolverhampton. The fatal cases of diphtheria, which had been 46, 44, and 60 in the three preceding weeks, declined to 46 last week, and included 12 in London and its suburban districts, and 3 each in Birmingham, Manchester, and Leeds. The deaths attributed to whooping-cough, which had declined from 55 to 25 in the three preceding weeks, rose last week to 30; 3 deaths were recorded in London, 3 in Manchester, and 2 each in Stoke-on-Trent, Birmingham, Burnley, Hull, and Rhondda.

The deaths referred to enteric fever, which had risen from 35 to 48 in the four preceding weeks, declined to 28 last week, and included 7 in London, 4 in Hull, 3 in Northampton, 3 in Birmingham, and 2 in Bradford. The fatal cases of scarlet fever numbered 18, against 10 and 13 in the two previous weeks, and of these 4 were registered in London, and 2 each in Walthamstow, Stoke-on-Trent, Birmingham, Leeds, and Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 2106 in the eight preceding weeks, had further advanced to 2180 on Saturday last; 297 new cases of this disease were admitted to these hospitals during the week, against 293, 355, and 344 in the three preceding weeks. These hospitals also contained on Saturday last 1148 cases of diphtheria, 177 of whooping-cough, 162 of enteric fever, and 84 of measles, but not one of small-pox. The 1132 deaths from all causes in London last week were 107 fewer than the number in the previous week, and included 210 which were referred to diseases of the respiratory system, against numbers steadily rising from 73 to 228 in the eight preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 170 and 150 in the two preceding weeks, rose to 158 last week, and 327 inquest cases were registered. The causes of 30, or 0·7 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Nottingham, Salford, and in 54 other smaller towns. The 30 uncertified causes of death last week included 7 in Birmingham, 6 in Liverpool, 3 in Sheffield, 2 in Stoke-on-Trent, and 2 in Gateshead,

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 771 births and 548 deaths were registered during the week ending Oct. 28th. The annual rate of mortality in these towns, which had been 16·4 and 15·7 per 1000 in the two preceding weeks, rose to 16·7 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 15·9 per 1000, and was 1·4 per 1000 above the mean death-rate during the same period in the large English towns. The annual death-rates in the Scotch towns last week ranged from 8·3 and 13·1 in Greenock and in Perth to 18·6 in Glasgow and 19·4 in Leith. The 548 deaths from all causes in the eight towns were 35 in excess of the number in the previous week, and included 52 which were referred to the principal epidemic diseases, against 74 and 47 in the two preceding weeks; of these 52 deaths, 19 resulted from diarrhœa, 12 from measles, 8 from diphtheria, 7 from scarlet fever, 4 from whooping-cough, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·6 per 1000, and was 0·5 per 1000 above the mean death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had been 33, 41, and 20 in the three preceding weeks, were 19 last week, and included 17 of infants under two years of age; 14 deaths were recorded in Glasgow and 4 in Dundee. The deaths attributed to measles, which had steadily risen from 1 to 9 in the four preceding weeks, further rose last week to 12, and comprised 8 in Aberdeen and 4 in Glasgow. The fatal cases of diphtheria, which had decreased from 13 to 5 in the four preceding weeks, rose to 8 last week, of which 5 were registered in Glasgow. The 7 deaths referred to scarlet fever were equal to the number in the previous week, and included 3 in Glasgow, and 2 Aberdeen. The 4 deaths attributed to whooping-cough were 1 fewer than the average in the three previous weeks, and included 2 in Glasgow. The fatal cases of enteric fever numbered 2, against 1 in each of the three preceding weeks, and were recorded in Glasgow and Perth respectively. The deaths referred to diseases of the respiratory system, which had averaged 79 in the three preceding weeks, rose last week to 111, and were 39 in excess of the number in the corresponding week of last year. Of the 548 deaths from all causes in the eight towns last week, 166, or 30 per cent., were recorded in public institutions, and 25 deaths were attributed to different forms of violence. The causes of 19, or 3·5 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 large English towns the proportion of uncertified causes did not exceed 0·7 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 524 births and 377 deaths were registered during the week ending Oct. 28th. The annual rate of mortality in these towns, which had declined from 19·6 to 18·6 in the three preceding weeks, further decreased to 17·1 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·7 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 14·5 per 1000, while in the eight Scotch towns it was equal to 15·9. The annual death-rate last week was equal to 18·0 in Dublin (against 13·1 in London), 16·7 in Belfast, 22·5 in Cork, 8·9 in Londonderry, 12·2 in Limerick, and 9·5 in Waterford; in the 16 smallest of these Irish towns the annual death-rate averaged 17·8 per 1000. The 377 deaths from all causes were 32 less than the number in the preceding week, and included 47 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 47 in the six preceding weeks; of these 47 deaths, 27 resulted from diarrhœal diseases, 9 from whooping-cough, 6 from measles, 2 from scarlet fever, 1 from enteric fever, 1 from typhus, and 1 from diphtheria, but not one from small-pox. These 47 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·1 per 1000. The mean rate from the same diseases in the 77 English towns did not exceed 1·1 per 1000, while in the eight Scotch towns it was equal to 1·6. The deaths attributed to diarrhœal diseases, which had steadily decreased from 121 to 31 in the six preceding weeks, further declined to 27 last week, and included 25 of infants under two years of age; 13 deaths were recorded in Dublin, 6 in Belfast, 2 in Londonderry, and 2 in Clonmel. The deaths referred to whooping-cough, which had averaged 2 in the four preceding weeks, rose to 9 last week, and comprised 5 in Dublin, 3 in Belfast, and 1 in Lurgan. The fatal cases of measles, which had been 2, 1, and 3 in the three preceding weeks, rose to 6 last week, of which 5 were recorded in Dublin and 1 in Cork. The deaths from enteric fever, typhus, and diphtheria occurred in Dublin, while those from scarlet fever were registered in Dublin and Belfast respectively. The deaths referred to diseases of the respiratory system, which had been 64, 50, and 66 in the three preceding weeks, declined to 57 last week. Of the 377 deaths from all causes in the Irish towns last week, 105, or 28 per cent., were recorded in public institutions, and 12 deaths were attributed to different forms of violence. The causes of 17, or 4·5 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·7 per cent. in the 77 large English towns, and was equal to 3·5 per cent. in the eight Scotch towns.

UNIVERSITY OF LONDON: FACULTY OF MEDICINE.—A meeting of the Faculty of Medicine was held at London University on Oct. 27th, Dr. Sidney H. C. Martin, Dean of the Faculty, being in the chair. The constitution of the boards of studies for 1912 with which the Faculty is concerned was duly arranged. A consideration of a report of the Board of the Faculty on the financial needs of the Faculty was adjourned. Dr. Leonard E. Hill having resigned his position as representative of the Faculty in the Senate of the University, a ballot took place to elect his successor. Two nominations had been received, and the result was as follows: Dr. Herbert Lightfoot Eason, 42 votes, and Mr. Henry Betham Robinson, 18 votes. Dr. Eason was declared to have been elected. The proceedings then terminated.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon H. Clift to the *Venerable*, on recommissioning. Surgeons: P. B Egan to the *Halcyon*, additional for the *Skipjack*, and J. D. Keir to the *Venerable*, on recommissioning.

ARMY MEDICAL SERVICE.

Colonel Herbert J. R. Moberly is placed on retired pay (dated Oct. 26th, 1911).

Lieutenant-Colonel Henry O. Trevor, from the Royal Army Medical Corps, to be Colonel, vice H. J. R. Moberly (dated Oct. 26th, 1911).

ROYAL ARMY MEDICAL CORPS.

Major Charles R. Elliott to be Lieutenant-Colonel, vice H. O. Trevor (dated Oct. 26th, 1911).

The undermentioned Captains to be Majors (dated Oct. 25th, 1911): Thomas E Fielding, Charles H. Straton, James M. Cuthbert, and Robert T. Brown.

Captain Herbert O. M. Beadnell is placed temporarily on the Half-pay List on account of ill-health (dated Oct. 17th, 1911).

Captain Alexander D. Fraser, from the Seconded List, is restored to the establishment (dated Oct. 24th, 1911).

Colonel R. H. Forman, principal medical officer of the Bombay Brigade, at present on leave of absence, has been struck off the strength of the Indian establishment, with effect from Nov. 2nd, on reaching the age limit. Lieutenant-Colonel T. B. Winter, senior medical officer in charge of recruiting duties in London, has been selected to officiate as Administrative Medical Officer of the London District, in succession to Colonel A. Peterkin, who has been retired on reaching the age limit. Lieutenant-Colonel H. M. Sloggett has taken up duty at the Military Hospital in Malta. Lieutenant-Colonel J. B. Wilson, in charge of the Surgical Division of the Royal Herbert Hospital, Woolwich, has been detailed by the War Office to proceed to Jamaica during the ensuing trooping season for a tour of foreign service. Lieutenant-Colonel T. McCulloch, in medical charge of the military hospital at Calcutta, has been appointed for duty on board the transport s.s. *Rewa*, which left Bombay for Southampton on Oct. 12th. Major G. S. McLoughlin, D.S.O., on the expiration of his appointment as medical inspector of recruits in the Western Command, has been transferred from Chester to the Southern Command. Major D. J. Collins has taken up duty as Specialist Sanitary Officer to the Dublin District. Major T. B. Beach, company officer of the 33rd Company of the Royal Army Medical Corps stationed at Cairo, has arrived home on leave of absence. Major B. F. Zimmerman has taken up duty at Lancaster as Medical Officer in charge of troops and their families. Major A. L. A. Webb has embarked for a tour of foreign service on the West Coast of Africa. An exchange of positions on the roster for service abroad has been sanctioned by the Director-General between Major L. P. More, serving at Portsmouth, and Major L N. Lloyd, D S.O., adjutant of the School of Instruction, London; the former will accordingly proceed to India for a tour of duty with the Northern Army. Major F. J. C Heffernan has left the London District for duty in India. Major A. H. Waring, from Portland, has taken up duty at the Military Hospital at Gosport as Officer in Medical Charge. Captain J. E. H Gatt has been transferred from Benares to the Station Hospital at Allahabad. Captain L. Bousfield, on the closing of Honiton Camp, has been posted to Devonport. Captain A. H. T. Davis, on completion of a course of instruction at the X ray institute at Dehra Dun, has joined for duty at Secunderabad. Captain J. M. H. Conway, from the Royal Infirmary, Phœnix Park, Dublin, has been selected for appointment as Adjutant to the West Riding Division, Royal Army Medical Corps, School of Instruction, at Leeds. Captain T. J. Potter, on return from special duty under the Colonial Office in Jamaica, has been posted as a Recruiting Medical Officer in London. Captain P. Sampson has been transferred from Sialkot to Upper Topa. Captain P. S. Lelean, specialist sanitary officer to the Seventh (Meerut) Division, has been granted one year's extension of his Indian tour of service. The following Captains have been detailed for the nine months' course of instruction for promotion to the rank of Major at the Royal Army Medical College, London, which commenced on Nov. 1st:—G. E. Cathcart, J. A. Turnbull, D. P. Johnstone, E. H. M. Moore, F. J. Garland, R. J. Cahill, S. C. Bowle, A. S. Arthur, P. Dwyer, H. T. Wilson, R. C. Hallows, G. A. D. Harvey, M. Sinclair, A. N. Frazer, H. St. M. Carter, K. A. C. Doig, P. A. Lloyd-Jones, J. St. A. Maughan, L. V. Thurston, A. W. Gater, J. P. Lynch, R. K. White, E. B. Booth, E. G. R. Lithgow, J. S. Pascoe, G. H. Richard, W. McConaghy, A. A. Sutcliffe, H. E Gotelee, E. J. Elliot, and J. H. Gurley. Lieutenant F. B. Dalgliesh, who is attached to the Station Hospital at Mhow, has been granted six months' leave of absence home from India.

INDIAN MEDICAL SERVICE.

Colonel H. Hendley, principal medical officer of the Sirhind and Jullundur Brigades, Lahore Division, has been selected by His Excellency the Commander-in-Chief in India for appointment as Deputy Principal Medical Officer of His Majesty's Forces in India in succession to Colonel D. ffrench-Mullen, whose tenure of the appointment has expired. Lieutenant-Colonel H. R. Woolbert, first-class agency surgeon, Bengal Presidency, has been granted six weeks' leave of absence. Major W. Selby, civil surgeon of Lucknow, has been placed on special duty in connexion with the Lucknow Medical College. Major H. J. Walton, civil surgeon at Bulandshahr, has been transferred in the same capacity to Saharanpur. Major C. Milne, on return from leave, has taken up the appointment of Civil Surgeon at Jhansi. The services of Captain N. S. Wells have been placed permanently at the disposal of the Government of the United Provinces of Oudh and Rohilkhand. Captain J. C G. Kunhardt, on special duty under the Sanitary Commissioner with the Government of India, has been granted three months' privilege leave of absence. Captain K. W. Mackenzie has been appointed Specialist in Midwifery and Diseases of Women and Children to the Fifth (Mhow) Division by His Excellency the Commander-in-Chief in India. Captain H. M. H. Melhuish has been transferred to Delhi as District Plague Medical officer. The services of Captain M. F. Reaney have been placed permanently at the disposal of the Honourable the Chief Commissioner of the Central Provinces by the Government of India. Captain A. S. M. Peebles has been selected for appointment as superintendent of the Central Asylum at Berhampore, Bengal Presidency, in succession to Major C. Robertson-Milne, deceased. Captain J. D. Sandes, officiating resident physician at the Medical College Hospital, Calcutta, has been granted privilege leave of absence for one month. His Excellency the Governor of Bombay in Council has been pleased to appoint Captain B. B. Paymaster to be a Civil Surgeon of the Second Class and to continue to do duty as Acting Civil Surgeon at Karwar. Captain E. J. C. McDonald has taken up duty in Eastern Bengal for civil employment and has been appointed to the Medical Charge of Sibsagar District, Assam. Captain C. A. Sprawson has been placed on Special Duty in connexion with the Lucknow Medical College. Captain R. Steen, civil surgeon, Bengal Presidency, has rejoined from study leave of absence. Captain A. G. Coullie has been appointed a Specialist in Advanced Operative Surgery. The services of Captain J. Buckley have been temporarily placed at the disposal of the Government of the Punjab for Employment on Plague Duty.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd South Midland Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Oct. 1st, 1911): Lieutenant James S. Mather and Lieutenant Thomas A. Green.

1st Northumbrian Field Ambulance, Royal Army Medical Corps: Lieutenant John M. Gover to be Captain (dated Oct. 1st, 1911).

2nd Southern General Hospital, Royal Army Medical Corps: Cadet Frederick Cecil Nichols, from the Birmingham University Contingent, Senior Division, Officers Training Corps, to be Quartermaster, with the honorary rank of Lieutenant (dated Oct. 25th, 1911).

Attached to Units other than Medical Units.—Captain Thomas A. Sellar to be Major (dated August 29th, 1911). Captain David Westwood resigns his commission (dated Oct. 25th, 1911).

THE JAPANESE NAVAL MEDICAL DEPARTMENT IN THE RUSSO-JAPANESE WAR.

The third instalment of the translation of the Japanese Naval Medical report on the late war by Dr. Chemin, staff surgeon in the French Navy, appears in the October number of the *Archives de Médecine et Pharmacie Navales* (O Doin, Paris, 2 francs), and should be read by every naval surgeon.[1] In the battle of the Yellow Sea (August 10th, 1904) the flagship, *Mikasa*, had an ambulance party of 26—12 men on the upper deck (of whom 9 were either killed or wounded), 11 down below, and 3 superintending petty officers. Of the 75 wounded who were treated at the dressing stations 42 walked down by themselves, 29 were carried down "man-handled," and only 4 came on stretchers. The wounded got a first dressing during the action at the dressing stations, which are in places protected indeed, because behind the armour, but very hot and stuffy. So after the battle the wounded were first removed to more convenient places, then taken one by one to the operating room and dressed again that night. After a first visit had been made next morning necropsies of those killed in battle were undertaken. For the battle of Tsushima (May 27th and 28th, 1905) most careful medical preparations were made by Admiral Togo and Surgeon-General Suzuki Shigemichi, who was also on board the *Mikasa*. As we have said before,[2] the principal medical officer of a Japanese fleet lives in the commander-in-chief's mess; that will in time be the case in our navy too. It was ordered that an abundance of dressings were to be prepared, and first-aid dressings to be put on deck in places conspicuously marked; they were also to be carried by stretchermen. Ice was to be available for treating contused wounds of important organs, and fans were to be provided to alleviate the discomfort of the wounded in the dressing stations, which of necessity in parts of the ship at any time hot are particularly uncomfortable in action with the hatches over them shut. It was considered well that men should bathe themselves before an action and put on clean clothes in case they are wounded. Spare operating blouses were to be ready for the surgeons. Stokers, especially in torpedo boats and destroyers, were to wear clothing covering them all over so that as little skin as possible might be exposed to the risk of scalding by escaping steam. It was not enough to give the men wadding to protect their ears from gunfire; medical officers were to go round before the battle and see the plugs were properly adjusted, not too loose nor too tight. Stretchermen were only to be on the upper deck when required; at other times they were to remain down below behind protection—i.e., armour. There was to be plenty of water for the wounded and they were to get as much to drink as they wanted. If in second-class cruisers and small craft ward-rooms were used as dressing stations, curtains and canvas were to be hung all round them to reduce damage by splinters. A nominal list of killed and wounded was to be forwarded immediately after, and men blown to pieces should be so noted in the column for remarks. In this battle the Japanese lost only 3¼ per cent. both killed and wounded, of whom ½ per cent. were killed. This section of Dr. Chemin's translation is full of information of the greatest value to every surgeon of a ship.

QUEEN ALEXANDRA'S NURSING SERVICE.

The regulations for this service for 1911 have just been issued. The limit of age for candidates is 35 and the pay as follows: Nursing sisters on entry, £40 per annum, rising by increments of £2 10*s.* yearly to £45; nursing sisters after three years, £50, rising by increments of £5 a year to £65; superintending sisters £70, rising by increments of £5 a year to £100; and head sisters £130, rising by increments of £10 to £160. The appointments are pensionable, and the head, superintending, and nursing sisters will be regarded as officers of the hospital, taking a position immediately after the surgeons.

ROYAL ARMY MEDICAL CORPS (TERRITORIAL FORCE): FIRST LONDON DIVISION.

The challenge cup for divisional field work, presented by Major E. B. Waggett, was competed for on Saturday last at Hendon. Three units competed, the 1st City of London Field Ambulance (Lieutenant-Colonel R. R. Sleman), 2nd City of London Field Ambulance (Lieutenant-Colonel J. Norwood Brown), and 3rd City of London Field Ambulance (Lieutenant-Colonel J. Harper). The competition consisted of a tactical scheme drawn up by Colonel B. P. Giles, C.B. (A.M.O. of the Division), on lines suggested by the donor, and included the entire operation of a complete section of a field ambulance under service conditions. The judges were Brevet Lieutenant-Colonel A. P. Blenkinsop and Major G. B. Stannistreet, R.A.M.C. The order was that each section should be formed up ready for work with transport at 4.30 P.M. However, the difficulties of getting men together, owing to their civil employment and the condition of London street traffic, prevented two of the units being on parade to time. At 4.30 to the minute the judges ordered the 1st Field Ambulance to commence. Later on the 2nd and 3rd Field Ambulance arrived, and, no objection being raised, also competed. As soon as it was dark the acetylene lamps and search-lanterns were used, and gave a very realistic representation of what happens in clearing the field of wounded at night. When the "Cease fire" sounded the judges gave their decision that the 1st Field Ambulance were the winners of the cup, the 3rd Field Ambulance being second, and the 2nd Field Ambulance third. The "Officers' call" was then sounded, and Colonel Giles gave the judges' decision and criticism. He complimented Captain A. Elliot, who was in command of the winning section, upon so successfully surmounting the difficulties of getting his transport through London at the appointed time. Captain Elliot had as his subalterns Lieutenant D. C. L. Fitzwilliams and Lieutenant Arthur D. Williams. It is understood that in future the competition will take place during the second week of annual training.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—As one opposed to any system of payment by fee may I be allowed as briefly as I can to state the grounds on which I base my objection and at the same time give reasons for my preference for the *per capita* system?

I hold one appointment (coastguards) in which payment is made by fee. The amounts received annually have varied over a period of 12 years from nothing to £4. Under the Post Office rate *per capita* I think I should have received more, but at least I should have been paid a fixed sum quarterly and been spared much anguish in making out returns, claims, and what not.

I hold the Post Office appointment under which payment is *per capita*. The pay order comes punctually at the quarter, and there is no fuss about it at all. The only return required is an annual report of the work done.

I hold several society appointments in which of course payment is also *per capita*, and here again it is like a salary should be—paid punctually; one knows the exact amount due, and the day it will be paid. There are no reports to make at any time—the clerical work is practically *nil*. Payment for union work is by salary and the amount of clerical work involved is considerable at times.

I have also a private surgery club for men, women, and children. Premiums I fix myself, and they vary according to age and my estimate of "health value."

An interesting calculation discovers the fact that half my income is derived from these appointments and that the members number *less than one third* of the total of my *clientèle!* The amount derived by "private practice" (including all confinement fees) from two-thirds of the total number of "my patients" is not more now than it was ten years ago, although the number has actually increased by at least 200 in that time. In the harvesting of one-half my income there is involved no making and sending out of bills, with all the worry attaching thereto, and it is only for the union portion of this half that there is any clerical work worth mentioning. For the other half, which comes from my "private practice," day-books, cash-books, and ledgers have to be posted, bills and receipts sent out, and heaven knows what besides. Of the total laboriously entered in my ledger every year I calculate that one-third will never be paid. There is ten times, perhaps 20 times, more clerical work required to get in this "private" half of my income than there is for the other. I have not got actual figures to show the number of visits made for each half of my income, but I

am convinced that there is less for the contract half than for the private, and I am certain there is far less worry. My relations with club patients, club officials, and guardians have always been perfectly agreeable, and everything runs smoothly from year to year. In regard to contract work, one's first and last wish is to get the patient off one's hands by getting him well in as short a time as possible, and there is no dread of being accused of making too many visits—there cannot be a glimmer of a suspicion in anybody's mind that you are going to the case too often. It seems to me this dread would with many of us operate strongly under any system of "payment by fee." There would always be people ready to accuse the doctor of this form of dishonesty—that is, making unnecessary visits (*vide Nineteenth Century*, July, 1911). This fee system is not only contrary to public weal, but I firmly believe is likely to be less remunerative, advantageous, and convenient to doctors than a system under which we shall be paid *per capita*, provided, of course, the premium is not less than the Post Office rate. One must remember that the sickness-rate is declining every year, that hospitals take operation cases off the private practitioner's hands, that in towns isolation hospitals rid him of his infectious cases, and that sanatoriums (if the Act is passed) will relieve him of his tuberculous cases. Various other agencies are at work in the community, which all tend to diminish our private practice—hospitals, patent medicines, medical advice in newspapers, popular medical books, ambulance and nursing classes, improved education, increased facilities of travel, diminishing birth-rate, &c. Every year the income derivable from a given number of the public is a diminishing quantity, and I am convinced that the only hope for the general practitioner is in extending his contract work.

Why the *per capita* system should be denounced as "immoral, dishonest, and demoralising" I fail to see. Should not the boot be on the other leg? (see *Nineteenth Century*). If these adjectives had been applied to the fee system—as they have been—I should have been less surprised. Speaking for myself, I have ofttimes felt "immoral" in charging 2*s*. 6*d*. for a visit to the sick child or wife of an agricultural labourer earning the munificent wage of 15*s*. per week, and I feel demoralised absolutely when I receive it, an event which happens occasionally. Are army and navy surgeons, medical officers of asylums, house surgeons and house physicians, school medical officers, medical officers of health, ships surgeons, doctors at such places as Hong-Kong, Canton, &c., all to be branded as immoral and dishonest because they work on a contract system and not by fee per visit? An asylum medical officer with 600 lunatics under his charge gets £150 a year whether there is much or little sickness amongst them. If he was paid 8*s*. *per capita* his income would be £240, and this is more than it probably would be if he was paid 2*s*. 6*d*. a visit. Some writers seem to think that *per capita* means per "sick person" instead of "per unit of working class."

If the fee system is adopted records of each case will have to be kept, accounts would have to be sent in and carefully scrutinised by officials, various returns would have to be periodically sent up, correspondence would arise over mistakes, or questions, or explanations, and the whole rigmarole would be a hideous nightmare. Under the contract or *per capita* system the necessary writing and the consequent worry would be reduced to a minimum. In my opinion if the capitation fee granted is adequate—and the Post Office rate should be the minimum—medical practitioners will gain largely under the Act. Its first effect will be to greatly diminish the annual total of bad debts we are all piling up in our ledgers. It will at 8*s*. *per capita* provide remuneration equivalent to 2*s*. 6*d*. per visit—without deduction for bad debts. We shall be rid of the ugly feeling which we must have all of us now and again experienced, that we are, by demanding our dues, depriving a poor sick person of what he needs to keep him in health. The effect of a *per capita* system of payment will not be to make us slack, indifferent, and inattentive to our patients, but just the contrary—keen and alert to prevent and active in curing—simply because it will be to our interest to prevent illness. For the first time in history (European) the interests of doctors and public will be at one.

I am, Sir, yours faithfully,

B. HALL, M.B. Lond.

West Mersea, Colchester, Oct. 30th, 1911.

To the Editor of THE LANCET.

SIR,—In a footnote to Dr. H. B. Luard's letter in THE LANCET of Oct. 28th, p. 1229, you say, "It is understood that a majority of the medical profession has given adherence to the principle" (of capitation payment); this understanding is surely a misunderstanding. The facts of the case are these: In spite of the special pleading in favour of the contract system set out in the March report of the British Medical Association, *the Divisions furnished a majority in favour of "payment for work done"*; notwithstanding this, the Representatives, disregarding the instructions of their constituents, adopted a policy of amending the contract system instead of ending it. This policy avowedly adopted on the ground of tactics ("not what we want, but what we are likely to get") has failed in this very particular, for whereas the demand for the abolition of contract, a system condemned by all investigators, including a Royal Commission, would have been found by public and Parliament perfectly reasonable and understandable, the demands of the six-point policy of the Association have gradually alienated the sympathy of the press and Parliament.

Finding that the executive of the British Medical Association was willing to lead them only half way to victory, the profession gave not their "adherence" but their encouragement and support, hoping that the Association would be stimulated to summon up pluck enough to do its duty. The six-point policy fails in duty on two sides. First, if the Association regards contract practice as an evil thing to doctors, patients, and to the practice of medicine (and the Association has declared it so), then it is its *duty* to demand its abolition when the intervention of the State renders it no longer necessary. Second, since the abolition of contract practice and the universalisation of the ordinary method of payment for work done do no injustice to the contract party, who all hold some private practice and are content with it, whereas the continuance of contract is a great hardship to the anti-contract party, who loathe the whole system, the Association fails in its *duty* of protecting the "rights of minorities" and fails most woefully in this case, since the "minority" is actually a majority.

Urged to be loyal and to avoid appearance of dissension in our ranks, we abolitionists have for some months kept quiet, trusting to bitter experience teaching our leaders that their demands were not only materially but tactically weak, and looking forward to the time (now at hand) when we should have an opportunity of pressing our views again on the profession. This opportunity arises from the failure of the Association's negotiations with the Government which must be followed by a long guerilla warfare; if the profession must fight we ask that a plebiscite should be taken as to what we shall fight for; and we are in no doubt as to the reply of the profession if the question is put clearly to it whether it will fight for semi-tolerable slavery (club practice amended) or freedom and justice (abolition of all contract and *insurance by medical men*).

Let this issue be put clearly, that contract practice is inherently and ineradicably bad, and can only be made tolerable by constant watchfulness in preventing abuses, a watchfulness which is extremely harassing and derogatory to medical men; and that payment for work done is the ordinary principle on which the affairs of society are run; and it will be found that there are few medical men willing that their business should be selected for the experiment of a reversal of this principle. Contract medical work is a combination of two separate businesses: one, medical practice; the other, underwriting or insurance. Are we as professional men desirous of combining with our profession the trade of financial speculation?

I trust, Sir, that you will not hesitate to accede to Dr. Luard's request, and register the names of those who declare themselves to be doctors, and only doctors.

I am, Sir, yours faithfully,

Bristol, Oct. 28th, 1911. HARRY GREY, M.D. Edin.

To the Editor of THE LANCET.

SIR,—In answer to the letter of Mr. Richard Williams in your issue of Oct. 28th. I beg to refer him also to the rules of the National Deposit Friendly Society, from which he will see that there is no analogy between the National Deposit Friendly Society and the scheme of the National Insurance

Bill, which latter caters for an entirely different class of the public.

The National Deposit Friendly Society combines the advantages of a Friendly Society with those of a savings-bank, and it provides sick pay, medical attendance, weekly old-age pay, permanent pensions, and assurances. The contributions of the members are from 1*s.* to 10*s.* per month, which entitle them to from 1*s.* to 10*s.* per day sick pay; in addition to the contributions they must, however, make deposits in the savings-bank department. When they draw sick pay a portion of it is deducted from their deposit account, thus preventing any kind of malingering, and the duration of the sick pay is automatically limited by the amount standing to the credit of a member in his deposit account. There appears to be no wage limit, but the sick pay must not exceed the usual earnings.

The society provides benefits for a much higher class of wage-earner than the ordinary club member, and every member has to pass a stringent medical examination before being allowed to join, extra rates being charged for impaired lives or those working in dangerous or unhealthy trades The society pays on the following scale of fees for attendances on the members: 2*s.* 6*d.* per visit, including medicine for two days; in dangerous cases requiring more frequent attendance, 1*s.* 6*d.* per visit for intermediate visits. The fee for attendance at a surgery is 1*s* 6*d.*, to include two days' medicine. In the case of the better-class members who are in receipt of sick pay between 5*s.* and 10*s.* per day, the medical attendance fees of 2*s.* 6*d.* and 1*s.* 6*d.* have an addition of 6*d.* for each 1*s.* received by a member over 5*s.* per day as sick pay. Mileage over two miles is allowed and very moderate extra fees for surgical cases and operations; these fees include the supply of apparatus, splints, medicines, and attendance for a month, and are, I think, wholly inadequate.

Such fees are perfectly possible to a society with the above rules, but I venture to ask any business man in the profession whether it would be possible to pay them out of an insurance fund dependent on a maximum subscription per assured member of 9*d.* per week, when unlimited continuing sick pay of 5*s.* per week is payable in cases of permanent and chronic disability, and members are admitted without medical examination.

Another of your correspondents, Dr. Edwin Smith, thinks that "there must be a capitation fee of 20*s.*, not a penny less." I would point out to your readers that this would mean an annual payment to the medical profession of over £15,000,000, and I should much like to know how it is proposed that such a sum could be raised. I think that the profession should remember that in the past it has given without stint an immense amount of gratuitous medical service; from this heavy burden it will be entirely relieved, for in future there will be no excuse for anyone asking for free medical attendance, since everyone unable to pay will be provided for. In view of this surely it will be possible to arrange a method of remuneration for medical men attending assured persons on a scale adequate but within the means of the Insurance Fund.

I am, Sir, yours faithfully,

South Hampstead, N.W., Oct. 28th, 1911. ALBERT BENTHALL.

To the Editor of THE LANCET.

SIR,—As I had in my early medical days a pretty large experience of club contract practice (one club 900 men, two lodges of Oddfellows, and four small societies) it seems to me impossible to speak too strongly against taking any contract pay for medical attendance. One of the Oddfellows for several consecutive years had more attendance than the whole payment from his lodge covered. The National Provident Society's record conclusively proves that it is possible to pay club doctors according to work done without financial breakdown.

I signed the British Medical Association's resolutions, as many others have done, without feeling in any way pledged to take contract work. Having for 20 years practised amongst a class of patients to whom the Bill applies, and finding that I should need four times the number of patients I now have to make the same income at Mr. Lloyd George's rate of pay, I have decided that I will not work under the Bill. I propose that those of the profession who feel the same, and consider that a decided stand against contract work should be made forthwith, form a "no contract society" without any further delay.

I am, Sir, yours faithfully,

New Kent-road, S.E., Oct. 31st, 1911. VERE G. WEBB.

To the Editor of THE LANCET.

SIR,—Mr. Lloyd George has said that the compulsory part of his scheme must provide that every person employed and whose income is up to £160 per annum must join the insurance scheme. Of course, there are also to be "voluntary" members, these to include all being paid an income by an employer. To illustrate the latter he says that a paid employee, such as a manager of the Bank of England, may become a member, and so obtain medical and other grants for 4*s.* or 6*s.* a year, which will, I trow, be bad for the bank managers, being something very akin to an insurance for death. Now I and others cannot pay for a good reliable assistant to treat these voluntary members. At least they can expect to get only 4*s.* worth of treatment for 4*s.*, just as they would give me only 20*s.* for a sovereign, and no more.

Mr. Lloyd George takes exceptional care not to state how we are to find out the real income from all sources of the "compulsory" member. Here lies the quackishness of his proposal. It may be suggested that as the freedom from paying income tax applies to those whose income from all sources does not exceed £160 per annum less insurance, and less the £10 opposite each child under 16 years, we could obtain a list of all those not taxed for income tax purposes. But such is nowhere provided in his Bill. It is said that about 15,000,000 compulsory contributors must become members. But as the official returns show that only 885,397 persons—excluding firms and companies—paid income tax, how are we to get to know what is the income of the 14,000,000 odd. This is a most serious point, and it is to be hoped that each doctor will call the attention of his M.P. at once to it. I would also point out that in so far not one of the points the British Medical Association has "demanded" has been granted by Mr. Lloyd George. Grave objection must be taken to the manner in which all our rightful requests have been ignored.

If we fail to obtain recognition of our requests then I trust each doctor will at once put himself and his local society into active touch with members of the House of Lords. I shall be glad to hear that some definite, honest, and practical solution has been given as to how the income of "compulsory" members is to be arrived at. If the National Insurance Bill passes in its present form it will mean a loss of at least £1,750,000 every 12 months to doctors.

I am, Sir, yours faithfully,

Liverpool, Oct. 31st, 1911. ROBERT R. RENTOUL.

To the Editor of THE LANCET.

SIR,—Perhaps you might explain the benefits to patients and medical men in the following cases.

On Sundays, when the shops of chemists and druggists are closed, how is medicine to be obtained by the public? In cases of patients coming to the surgery suffering from pneumonia or diphtheria, they will have to go on to the chemist, and perhaps, on busy nights, stand about for half an hour till their prescriptions are made up. In some cases the patient may have a mile or more to walk. Again, in cases of night visits, how is the patient to proceed?

Perhaps you may be able to show the way out of this *impasse;* but I can see only one—viz.: The medical man, unless he is allowed to make up his own medicines and is paid for same, will be forced for common humanity's sake, to give some 30 per cent. of his time and drugs free.

I am, Sir, yours faithfully,

Endymion-road, N., Oct. 31st, 1911. S. CONSTABLE.

*** Our correspondent details one of the difficulties in removing dispensing from medical hands, but we must presume that with the altered circumstances new facilities will arise.—ED. L.

To the Editor of THE LANCET.

SIR,—I read with much astonishment your note at the end of Dr. H. B. Luard's letter in last week's LANCET and should like to learn on what evidence you conclude that the medical profession has accepted the "incalculably wide extension of the contract system proposed under the National Insurance

Bill." I feel convinced that the bulk of the profession, at any rate in the North of England and Scotland, have no intention of accepting such a thing under the Bill, and if you were to peruse the various resolutions which have been passed at the meetings of the local divisions of the British Medical Association you would find that many divisions have passed resolutions that service under the Bill should only be accepted on the basis of payment for work done. When the history of the profession for the past year comes to be reviewed it will seem almost incredible that a learned profession should have shown such a lack of common sense in the attitude it took towards the medical benefits of the Bill.

The British Medical Association sent out a list of questions to be answered in respect to a proposed Insurance Bill before the text of the present Bill was published. Alternative questions were given as to the methods of control and payment under a proposed insurance scheme for medical benefits, and naturally these were answered under the impression that such a scheme would only be applied to the submerged tenth above the pauper line, and many divisions thought that all the questions must be answered. This, in my opinion, is the first mistake the profession (or the Association on behalf of the profession) made, and I feel sure that if the opinion of the profession were now to be taken as to whether they will accept such an extension of contract practice, the replies would be in the negative.

In the six minimum requirements formulated by the Association there is no mention of contract practice or *per capita* payment; the remuneration is to be adequate, and the method of remuneration in accordance with the wishes of the majority of the profession in each locality. Even if these minimum requirements are insisted on the profession can theoretically choose the method of payment; practically I am afraid the "Battle of the Clubs" will have to be fought over again with a Government scheme in place of the Friendly Societies as the enemy. The general opinion of the profession, so far as my opportunities have allowed me to judge, is that up to the present the Association have managed things very badly, and if in face of the reports of the Poor-law Commission, of THE LANCET, and of the *British Medical Journal* condemning contract practice the Association should now countenance contract practice in the present Bill it will receive the heaviest blow it has ever received, and the profession will cease to regard it as a body able to protect professional interests, and the recent increase of membership will be followed by a still more remarkable decrease. I would ask you to take steps to gauge the opinion of the profession as suggested by Dr. Luard, and the results will convince you that the profession are not willing to accept such an extension of contract practice.

I am, Sir, yours faithfully,

Oct. 30th, 1911. F.R.C.S. ENG.

To the Editor of THE LANCET.

SIR,—I have read with interest the numerous letters on the National Insurance Bill and have noticed how many of them advocate payment for work done, say, on the lines of the National Deposit Society, but have never seen one showing why this is impracticable, although many make such statements. I think there is little doubt that the large majority of us, and probably all, would be in favour of payment for work done, if it could be managed, and I cannot see why such a scheme should be at once condemned as being out of the question. I believe I am correct in stating that the actual cost for medical attendance on the National Deposit system works out at a fraction less than 4*s.* per head per annum; and although admitting that the fees are too low, I think every one of us would rather work on some such lines than under the much condemned *per capita* system. Among the points for and against that have arisen on talking the matter over with other men are the following:

Con.: 1. That in a long illness a patient runs through his deposit. This is so, but with the addition of the employer's and State's shares it would be much less likely, and even so he could still receive the 5*s.* a week the Insurance Bill offers. 2. That too many visits might be paid by the doctor, but since these are paid for out of the patient's deposit, there would be the same deterrent effect as at present under the National Deposit system. I think that anyone who has tried both will agree that he sees far fewer trivial cases and pays far fewer unnecessary visits under the National Deposit than under the ordinary club system. 3. The filling up of the necessary forms, but this is really very little trouble and would soon become a routine.

Pro.: 1. That we should all prefer payment for work done. 2. That such a system carries with it free choice of doctor. 3. That we should not have the many trivial and unnecessary calls we now have under the ordinary club system. 4. That it would probably be possible to vary the fees according to the patient's income.

I am, Sir, yours faithfully,

Parkstone, Oct. 31st, 1911. K. M. GIBBINS.

THE STRIKE AND THE DEATH-RATE IN LIVERPOOL.

To the Editor of THE LANCET.

SIR,—The lengthy report of your Special Sanitary Commissioner on the supposed connexion between the recent strike in Liverpool and the severe epidemic of infantile diarrhœa which raised the death-rate in that city during the months of July, August, and September has interested me greatly because I have been defending the position in the lay press of Liverpool that the strike and epidemic were wholly unconnected.

As medical men we have no concern with the causes of the strike, or even with the methods of the strike, but the question whether, as alleged, the strike did accentuate the epidemic has a great scientific interest, especially if the comparative figures in Liverpool and elsewhere show, as I believe they do, that the presence of garbage in the streets had no effect on the epidemic of the disease, thus indicating that it is carried in some other way than by means of garbage.

Your Commissioner starts with the assumption that the strike is responsible for the enhanced death-rate and states that "the death-roll is not yet closed." Such a method of procedure is a mere begging of the question until it has first been proven that the strike actually did produce an effect. I submit that all proof of this is lacking either in your Commissioner's statements or in the statistics given in the report of the medical officer of health for Liverpool. In discussing the question I should like throughout to compare the figures for Liverpool with the figures for Dublin, choosing the latter city because it was free from any general strike at the period in question. The population in the Dublin area is just about half that of Liverpool, so that for comparison the Dublin figures should be doubled.

Your Commissioner makes a great point of the fact that the figures were very low in July and states that there was only a small increase up till August 7th, which he places quite arbitrarily as the date of the strike. By that date, he claims, "the great strike had thrown all the sanitary services out of gear." Now this I emphatically deny, for the scavenging service was not materially disturbed until August 16th till August 19th, the period of the general railway strike, and for a few days thereafter. As to the small figures, in July and early August, giving promise of a mild epidemic in Liverpool, in the first place, I contend, they are not small, and in the second place that they were proportionately much higher than those obtaining in Dublin, where nevertheless there was a heavy epidemic in August and September without the intervention of any strike. Thus, the figures for the four weeks in July for Liverpool were 20, 23, 38, 46, while for Dublin they were 4, 5, 11, 34. For the first four weeks in August Liverpool ran 81, 132, 159, 140, while the Dublin figures were: (week ending) August 5th, 29; August 12th, 41; August 19th, 49; August 26th, 38; Sept. 2nd, 51. For the first four weeks in September the Liverpool figures ran 148, 130, 109, 112; while the Dublin figures for as close dates as available were: (week ending) Sept. 9th, 45; Sept. 16th, 46; Sept. 23rd, 43.

With the single exception that the epidemic throughout, both before, during, and after the strike, is somewhat more severe in Liverpool than in Dublin, there is no difference in the two cities. The curves of incidence are identical in form, and there is no perturbation in the Liverpool one to indicate a strike or other contributory cause. It is also to be remembered that Liverpool is usually one of the most severely stricken centres in any severe year of epidemic diarrhœa. It is entirely without meaning to compare the four or five cold wet summers preceding this last summer

with it, as your Commissioner, copying the medical officer's report, proceeds to do.

Since the increase in the general death-rate was nearly all due to the epidemic of diarrhœa, it would be a waste of space to follow through this, but it appears to me peculiarly absurd for your correspondent to draw attention specially to the small fluctuations in the general death-rate to the end of the fourth week in September and then remark that "these figures clearly indicate that the exceptionally hot weather did aggravate the situation, and that the strike intensified the evil to an alarming and disastrous extent." The modest estimate is then made that for a period of two weeks a third of the deaths from diarrhœa were due to the strike. One cannot help wondering which two weeks these were, and how the "one-third" was arrived at; there is an uncanny precision about it that alarms one. The part of the strike which really interfered with scavenging for a few days occurred in the third week in August. Let it be granted that this aggravated the amount of infection and made more children ill with the disease, then these children have to sicken, pass through the course of the disease, and die before any effect is visible on the weekly death-rate. The very earliest week, therefore, in which the death-rate could show any effect due to the strike would be the fourth week in August, or more probably the first week in September. But in these weeks the epidemic had already commenced to show abatement: how then does your Commissioner arrive at his mathematical one-third of the deaths due to the strike? The only point in favour of an influence of the strike on the epidemic is the slow decline of the disease in September, but this is equally slow in Dublin where there was no complicating strike, and in both cases the most obvious reason is the mild character of the September weather.

To sum up, the epidemic was well on its way and already past its maximum before it could possibly have been influenced by the strike, and there is not one respectable shred of evidence that the strike had any influence upon it. Yet, as a consequence of this report, one finds the workmen accused in the lay press and in a vast mass of municipal election literature of massacring their own children. There are indications about that one of these days the medical profession itself may not be far from something closely resembling a strike, and much as many of us may rightly deprecate certain of the methods of the recent strike, we ought surely to have some meed of sympathy for men striking for a reasonable living wage for themselves and their wives and families. In any case, from the purely professional point of view such scares raised upon entirely inadequate evidence are, in my opinion, much to be deprecated.

I am, Sir, yours faithfully,

Liverpool, Oct. 30th, 1911. BENJAMIN MOORE.

DR. CUTHBERT MORTON'S "PRINCIPLES OF ANATOMY."

To the Editor of THE LANCET.

SIR,—With reference to the review of my work, "Principles of Anatomy: The Abdomen Proper Described and Illustrated by Text and Plates," which appeared in THE LANCET of Oct. 21st, I should like to say that when a scientific work, bearing the visible imprint of years of hard and conscientious labour, is submitted to a scientific journal for review the reviewer is under an obligation to furnish the author and the publisher of the work, as well as the editor and the readers of the journal, with a scientific expert criticism, that is to say, an accurate and clear statement of what the work aims at, how far it attains its aim, and what scientific worth or practical value it possesses or is likely to possess either in its present or in any probable future form. Casual criticism is entirely out of place.

Your reviewer has noted some resemblance in appearance between the "Principles of Anatomy" and Snellen's test-types. I should like to draw attention to a certain resemblance in function also, for just as the keenness of a man's physical vision may be tested by learning from himself how much he is able to see in Snellen's test-types, so the keenness of a man's mental vision may often be gauged by learning from himself how much he has been able to see in a work which he has reviewed. Your reviewer has seen in the "Principles of Anatomy" only "14 drawings"; your readers will find 14 front-and-back plates with at least two drawings for each. He has seen only "outlines"; they will be struck by the details. He has seen that "the outlines all coincide, and when held up to the light in the special frame provided may be superimposed and viewed as transparencies"; they will perceive that outlines which all coincide may be superimposed but cannot be viewed as transparencies with profit. He has seen only "various organs in their relation to each other and to the surface of the body"; they will perceive that, *inter alia*, every organ of the abdomen proper can be studied in its surface anatomy, its parietal, visceral, and peritoneal relations, and its blood- and lymph-vascular and nervous supply. He has seen in some pages of the text an appearance "irresistibly suggestive of Snellen's test-types"; they will perceive that these pages are to be found only in the Table of Contents, where their "strange variety of type" serves a definite and useful purpose. He has seen, quoted, and criticised what "the author says of the purpose of the work"; they will perceive that in their original context on p. 6 of the Principles the words quoted are strictly relevant, referring as they do in the clearest and most unmistakeable manner solely to the presentation of the body by plates. The introductory lines of apology (which, as he truly remarks, have been culled from John Bunyan's Apology for the "Pilgrim's Progress") he has seen to be of sufficient importance to require in the review as much space as either the plates or the text, and he is even "tempted to wish that the author had quoted more fully from the Apology of the 'wonderful tinker,' and added the lines—

> 'If that thou wilt not read, let it alone;
> Some love the meat, some love to pick the bone.'"

Your readers will perceive that the "wonderful tinker" (and the author, too) has long anticipated both the verdict of your reviewer—

> "Well, yet I am not fully satisfied,
> That this your work will stand, when soundly tried,"—

and the author's reply—

> "Be not too forward, therefore, to conclude,
> That I want solidness,—that I am rude;
> Nay, since your brethren pleased with it be,
> Forbear to judge till you do *further see*.
> If that thou *wilt not* read, LET IT ALONE;
> Some love the meat, some love to pick the bone."

I am, Sir, yours faithfully,

WM. CUTHBERT MORTON, M.A. (Classical First), M.D. Edin.,
Honorary Demonstrator of Anatomy in the University of Leeds.

Leeds, Oct. 28th, 1911.

THE NOMENCLATURE OF SPINAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—Mr. Paul B. Roth and myself disagree upon one very distinct point. He, following Lovett's deductions and the suggestion of W. Adams, believes that the spine is incapable of any simple lateral movement whatever, and that even in the normal subject rotation is coincident with the very beginning of side-bending. To him, therefore, the terms "lateral curvature" and "skoliosis" are synonymous. I hold a very firm opinion that lateral movement in the dorsal region is free until all play in the costo-vertebral articulations has been taken up and that rotation commences only when the tubercles of the ribs become firmly applied to the tips of the transverse processes. To me, therefore, the terms "lateral curvature" and "skoliosis" are *not* synonymous, for the first stage of the former may be quite free from any rotation whatever. The extent of this free stage varies with the type of patient, being very brief in the "rigid" type and much greater in the "loose-jointed" type. Its existence in the latter type has been noted again and again by old writers, who verified their observations by the use of some such instrument as Barwell's skoliosis gauge, and who adopted the term "lateral deviation" to fit this pre-skoliotic phase of lateral curvature.

However, Mr. Roth and myself can meet on common ground by putting aside the terms "skoliosis" and "lateral deviation" altogether, and by using the term "lateral curvature" to cover all phases of all cases. The classification he supports then works out as follows:—1. Postural lateral curvature. 2. Osseous lateral curvature in four stages—trace, moderate, severe, and extreme. The diagnosis between

the "postural" and "osseous" cases presents no difficulty, and is too well known to call for any description, but the subdivisions of "trace," "moderate," "severe," and "extreme" leave too much to individual judgment. They are excellent terms to use to the patient's friends, but are too vague to find acceptance if any more precise classification is available. I maintain that we have this in the method of Professor Rudolf Klapp and Dr. Fränkel of dividing all cases into three grades, each easily recognisable, and each resting upon a definite anatomical basis.

There is no need to repeat the analysis of these three grades given in my letter published in your issue of Oct. 14th, but Mr. Roth misapplies to them my description of the three distinct stages in the underlying anatomical changes in the thoracic skeleton. My correct statement regarding the three clinical grades of cases was as follows: "These grades pass imperceptibly one into the other. ..... But, with experience in examination, there is little difficulty in relegating any one case to its proper grade: the distinction is about as definite as that between degrees of burn." The truth of this comparison is a strong argument in favour of this method of classification.

Mr. Roth has some difficulty in understanding the second grade of case in which the bones have not yet undergone any fixed alteration in shape and in which the deformity, rendered possible by the elasticity of the ribs and their cartilages, is maintained in great measure by muscular and ligamentous shortening holding the contorted thorax in malposition. There is no mystery about lateral curvature of the spine and the soft parts behave as they do in other deformities—viz., the muscles and ligaments will become shortened or lengthened according to diminished or increased strain. Thus they will be shortened on the concavities of the curves and lengthened on the convexities. It was in recognition of this phase and of the importance of restoring the mobility of the thoracic framework that the "creeping" exercises were devised, and therein lies the explanation of the excellent results derived from them.

I am, Sir, yours faithfully,

Cavendish-place, W., Oct. 28th, 1911. J. S. KELLETT SMITH.

THE ETIOLOGY OF SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 28th you publish a communication from Dr. R. W. C. Pierce, medical officer of health for Guildford, on the subject of the Etiology of Scarlet Fever. In the communication he mentions that I called the attention of Dr. J. C. Thresh, medical officer of health for this district, to the fact that I had a sequence of four sporadic cases of scarlet fever, in each of which there was a septic wound or a septic condition of some sort. The cases were as follows: 1. A boy, aged 9, sleeping and living amongst five other young children, developed a typical scarlet fever rash, throat and tongue. It was not possible to move him until two days after I had diagnosed his condition, so that he had to remain amongst the other children. None of them caught it. He had an abscess and a septic condition of the sole of the foot. 2. A young lady had had her ears pierced and the wounds became infected. About 14 days afterwards she developed a rash very like scarlet fever and undoubtedly connected with the septic condition of the lobes. This certainly was not a *typical* case of scarlet fever. 3. A child of 8 showed a typical scarlet fever rash. She lived in an isolated cottage and had not been near other children or people for several weeks. She had a septic sore from an abrasion on the front of the tibia. 4. A young woman had a lot of teeth removed under gas for pyorrhœa alveolaris. She developed scarlet fever a few days afterwards.

These four cases, occurring one after the other, long distances apart, arising from no previous cases as far as I knew, and giving rise to no fresh cases in their own homes as they were either isolated at home or sent to the fever hospital before the peeling stage, made me think whether there was a condition common to them all to account for the onset. The common condition to all I found was a septic one on some part of the body.

Until such a condition is found to be present in a large percentage of sporadic cases in sparsely populated districts the observation is not worth much. It would be interesting to hear other medical officers of health on the subject.

I am, Sir, yours faithfully,

Stock, Ingatestone, Oct. 30th, 1911. HERBERT CARDIN.

OLD AND NEW VIEWS ON THE TREATMENT OF CONSUMPTION.

To the Editor of THE LANCET.

SIR,—Dr. C. Theodore Williams in his excellent Harveian oration on the new views on the treatment of consumption, published in your last issue but one, mentions that 54 different theories have prevailed in bygone ages—that is, from the time of Hippocrates to the time of Dr. Hughes Bennett. And these theories are as diverse as they are numerous, and testify to the lively imagination of their authors, and, as a rule, mistake predisposing causes for the *causa vera*, which, "though long suspected, was never actually discovered till Robert Koch appeared on the scene." May I be permitted to mention an addition to the list, and which, I believe, surpasses all others in value, and is a piece of work of equal magnitude with Koch's own, which it preceded by almost 14 years. I mean, "Études sur la Tuberculose: Preuves rationelles et expérimentales de sa spécificité et de son inoculabilité. Par J. A. Villemin, professeur agrégé à l'École Impériale du Val-de-Grâce, 1868; à Paris, chez J. B. Baillière et Fils, éditeurs." The 17me Étude is a most remarkable production; any one having read the work will believe that Villemin listened to the exhortation of "l'immortel Harvey," as we say on this side of the Channel, "to search and study out the secrets of Nature by way of experiment," and that he did it successfully.

I am, Sir, yours faithfully,

Paris, Oct. 30th, 1911. EUGENE DUPUY.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Physical Defectives.

A SPECIAL subcommittee of the Birmingham Education Committee has issued an exhaustive report concerning all cripples in the city, both adults and children. It has taken the committee two years to tabulate and collect the facts. The object was to find out why people became cripples, what could be done to prevent it, how cripples earn a living, and in what trade they are most successful. The answers to these questions are given at some length. There are 1001 cripples (546 males and 455 females) over 16 years of age. Of these 334 (212 males and 122 females) are being maintained by the three local boards of guardians, 180 being in infirmaries and 154 in workhouses. In the Birmingham workhouse and infirmary out of a total of 2636 inmates 272, or 10·3 per cent., are cripples. Of the 1001 cripples in the city about one-fifth, or 214, were able to work under ordinary conditions, and 145 could do some useful and remunerative work if workshops could be provided in the centre of the city. They were not so handicapped that they could not go to and from their work, but they could not compete with ordinary workmen. Employers were loth to engage them. The third class, 111, were unable to go to and from a central workshop. The Cripples' Union was doing a great work, but had not sufficient funds to cover the ground. The last class, comprising 531 cases, could do no remunerative work, and 334 of these were maintained by the guardians. There were 728 cripples under 16 years of age, some of whom will recover, but the committee did not think this number would be large. Mrs. Hume Pinsent, in presenting the report to the Education Committee, said she believed it was the first report of the kind ever made in England. She appealed to the medical profession to read the report and see if they could give satisfactory answers and information on the questions asked. Dr. H. W. Pooler pointed out that the great majority of cases of tuberculosis of the bones and joints were due to infection from food, chiefly milk, which children took in their earlier years.

Greater Birmingham and Special Schools.

None of the outside districts about to be taken into the city have made special provision for defective children with the exception of Aston, which has a small school for the deaf. The other districts send most of their deaf children to institutions, and in all the districts blind children are sent to institutions. The percentage of defective children in the school population will probably not differ materially in the new districts from the percentage known to exist in the old

Birmingham area. In the present city, with a school population of 96,260, there are 1093 mentally defective, of whom 832 are in day-schools, 51 in residential schools, and 210 for whom further accommodation is required. Further accommodation is also required for 63 cripples, 33 epileptics, and 20 partially blind children. In the outside districts it is estimated that there were 826 defectives for whom accommodation must be gradually found.

Oct. 30th.

NEWCASTLE-ON-TYNE.

(FROM OUR OWN CORRESPONDENT.)

Stannington Sanatorium: Opening of a New Wing by Earl Grey.

ON Oct. 29th there was formally opened a new wing of the Children's Sanatorium at Stannington. More than ordinary interest was attached to the ceremony of opening. In the first place, the expenditure for the erection and equipment of the extension was entirely defrayed by the Lord Mayor of Newcastle-on-Tyne, Sir William Stephenson, and the new wing has been named the Lady Stephenson Wing in consequence. The institution itself is an off-shoot of the work of the Poor Children's Holiday Association, which also manages a convalescent home on the same land for children recovering from debilitating diseases; here one must also mention the presence of a neighbouring farm, also under the auspices of the Poor Children's Holiday Association, worked by youths who have been rescued from a street life. Rather more than a year ago Sir William Stephenson wrote: "It has constantly been in my mind that the building ought to be completed by the erection of an additional wing, and thus provide accommodation for 50 more patients"; and following on this he made his gifts as mentioned above. In the second place it is interesting to note that these additional beds will be devoted to patients suffering from local tuberculosis, of joints, bones, and glands, for whose relief up to the present there has been no provision in the sanatorium. And, thirdly, interest attaches itself to the fact that the opening by Earl Grey was his first public service since his return from Canada after his seven years' governor-generalship. At the ceremony Earl Grey was supported by Sir William Stephenson, Miss Stephenson (the Lady Mayoress), Lord Armstrong, Sir Walter Plummer, Lady Ridley, Sir Riley Lord, the Right Hon. Thomas Burt, M.P., and Mrs. Burt, Dr. T. M. Allison, Mr. J. H. Watson (honorary secretary), and many others. Earl Grey received a gold key from the Lady Mayoress and opened the door of the new wing, after which a dedication meeting was held in the large dining-hall. In the course of his remarks the noble chairman said that he had had no hesitation in replying from Ottawa, where he had received the invitation for the ceremony, and accepting the invitation; the character of the association made him regard its operations as doing some of the best work for the public in the north of England. They were often told by scientists that that country which had a large amount of consumption among its population was an uncivilised country, and that if only the lives of the people could be regulated on scientific lines they should make consumption as obsolete a disease as leprosy was to-day. It was possible for them to banish it from the land if they only tried. The Lord Mayor, in thanking Earl Grey for his kindness and presence, asked to be allowed to present to his lordship a small gift of silver plate. This took the form of a tray with a suitable inscription thereon, and also an engraving of the new wing. Earl Grey suitably replied. Votes of thanks to Earl Grey and to the Lord Mayor concluded the proceedings.

Care of the Teeth: Step by the Northumberland Education Committee.

The Northumberland education committee meeting at the Moot Hall, Newcastle-on-Tyne, last week considered a report dealing with the results of a circular letter, which had been addressed to the managers of the elementary schools, inviting attention to the remarks of the school medical officer in his report of last year relative to the injury likely to arise from carious teeth. The managers were asked to state their views after consulting the head teachers on the likelihood of scholars purchasing at the school toothbrushes if supplied by the committee at cost price, and, further, as to the practicability of the scholars using the brushes at the schools. Replies had been received from 39 schools, and whilst in three cases the managers stated that in their opinion no action was necessary, and in one case it was stated that all the children used toothbrushes in their homes, the majority were in favour of inviting the children to purchase brushes, but, as a rule, considered it was impracticable for them to be used at the school premises. It was agreed by the committee (1) that a supply of toothbrushes should be purchased out of the voluntary fund which had been raised for the provision of spectacles and sold at cost price to the scholars asking for them; (2) that it be left to the managers and teachers to arrange for the brushes to be used by the children; and (3) that a circular drawing attention to the importance of cleaning the teeth be prepared by the school medical officer and issued with the brushes.

Oct. 31st.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Pauperism in Lampeter.

THE Lampeter union has a decreasing population of about 9000 persons, and at a recent meeting of the board of guardians Mr. Hugh R. Williams, one of the Poor-law Inspectors of the Local Government Board, drew attention to the much higher cost of pauperism in the union than in the adjoining districts. The cost per head of paupers in Lampeter had increased from 5*s.* to 5*s.* 6*d.*, whereas in the Tregaron union the cost per head was 4*s.* 5*d.* He suggested that the guardians of the unions in Cardiganshire should consider the practicability of carrying out a more extended classification of those paupers who were in institutions by utilising one workhouse for adults, another for children, and another for the weak-minded. In the early days of Poor-law administration there was a workhouse in each parish; these soon gave place to a combination or union of parishes with a joint workhouse, and now it would appear to be desirable to have a combination of unions.

Welsh Tuberculosis Campaign.

There has now been promised to the funds of the Welsh National Memorial nearly £200,000. This is to be utilised in every reasonable manner that can be devised for preventing tuberculosis, and an influential deputation is waiting upon the Chancellor of the Exchequer asking that Wales and Monmouthshire should be constituted a unit for providing sanatoriums and administering sanatorium benefits under the National Insurance Scheme. So far the efforts of the promoters have been concentrated on methods of education by means of popular lectures, a travelling exhibition, and the spread of popular literature. A further step has now been taken in the direction of treatment. A small sanatorium has been presented to the Memorial Fund by Miss A. M. Davies, who erected it a few years ago and has since maintained it in the county of Anglesey. In Newtown, in the county of Montgomery, there is in course of erection the first tuberculosis dispensary to be established in North Wales. The entire cost is being borne by Mr. David Davies, M.P., who was the originator of, and a most munificent contributor to, the Memorial Fund. He intends to place it at the disposal of the fund when completed, and it will presumably be administered in conjunction with the Montgomeryshire Infirmary at Newtown, the new buildings for which have only recently been opened. The dispensary, which has been carried on in a basement room in the Cardiff city hall for more than a year, under the assistant medical officer of health, Dr. E. Fairfield Thomas, as medical officer, has established for itself a definite place in the public health equipment of the town. There are over 1000 names of patients on the books of the dispensary, and the results of the enterprise are said to be very encouraging.

Housing Schemes.

The Merthyr corporation was one of the earliest to embark on a municipal housing scheme, and it has now decided to purchase an estate 92 acres in extent at a cost of £12,000. It is intended to erect on it about 300 workmen's dwellings, many of which will be required to replace houses which ought no longer to be occupied, but of which the occupants cannot find better dwellings. At Bedwellty, an urban district

of Monmouthshire, the population of which has increased from 10,000 in 1901 to over 22,000 in 1911, there has for some years been a serious dearth of houses, but there seems at last to be some prospect of an amelioration of the existing unsatisfactory conditions. The district council has decided to build 60 houses, and nearly 500 more are to be erected by the Welsh Garden Cities Syndicate on a site of 40 acres. The scheme of the syndicate enables the tenant of a house to purchase it on payment of an initial sum equal to 20 per cent. of the cost of construction, the remaining 80 per cent. being paid in weekly sums amounting to less than the rental that would ordinarily be charged for such a house.

Diphtheria in Cardiff.

In a recent report to the Cardiff school management committee Dr. E. Walford, the medical officer of health and school medical officer, stated that during the first nine months of the present year there had been 334 cases of diphtheria in the city and 24 deaths. In the corresponding period of 1910 there were 236 cases and 12 deaths. As in former years, the chief incidence of the disease has fallen on children at school ages, and it is probable that the assembling of children in the public elementary schools at ages when they are particularly susceptible to infection has been a factor in spreading the disease. Facilities are afforded at the public health laboratory for the examination of specimens from the throats of suspected children and from convalescents, but Dr. Walford expresses regret that greater use is not made of these facilities by the medical practitioners of the town.

Oct. 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh: Meeting of the General Council.

THE statutory meeting of this body was held on Oct. 27th in the University. Sir William Turner, K.C.B., Vice-Chancellor, presided. The first business was to appoint two assessors to the University Court: Dr. R. McKenzie Johnston, whose term of office had expired, was reappointed; and Mr. George A. Berry, President of the Royal College of Surgeons, was appointed in room of the late Dr. Joseph Bell. Mr. J. B. Clark, convener of the business committee, submitted a minute regarding Dr. Bell's death, in which, in addition to the qualities for which he was so widely known, his devotion to duty, and particularly to his duty as one of the General Council's representatives on the Court of the University, his conspicuous business ability, sound judgment, and natural quickness were eulogised. It was intimated that the University had recently decided to grant a Diploma in Psychiatry, which will be open to any registered medical practitioner who completes the necessary course of study. The diploma is intended for those who propose to devote themselves to this branch of medicine. The course of study will extend over one academic year. Candidates who have held responsible asylum posts for not less than two years may be exempted from one or more subjects of the curriculum. The opening of this diploma to all medical practitioners is one of the first-fruits of the recent medical ordinance giving the University greater freedom of action than it had formerly. The only other matter of medical interest brought before the Council had reference to the inclusive fee proposals. The convener of the business committee intimated that the University Court had agreed to its representation that if an inclusive fee were established the cost of study to the student should not be increased; he at the same time proposed that the Council should take no further action in the matter at present, as it was undesirable to hamper the dealings of the University with the Treasury. It was decided, however, to send to the University Court the findings of the conference of representatives of the general councils of Scottish Universities which had met in July. The findings were briefly as follows: The conference did not approve of the principle of inclusive fees; that if it was forced students should have the option of paying individual class fees as at present. Apart from Arts, the conference had not sufficient data to enable it to suggest the amount of the inclusive fee; that whatever system be adopted in the Faculties of Medicine and Science care should be taken to safeguard the interests of the extramural schools; that in the case of a student presenting a qualifying certificate from an extramural class his inclusive fee should be reduced by that amount. It was then proposed and agreed that the meeting be postponed, as there were certain important matters to be shortly sent down from the University Court for the consideration of the Council. The date of meeting was left in the hands of the business committee.

The British Medical Association and the Insurance Bill.

On Oct. 28th a meeting was held in Edinburgh to consider the prospects of the profession with regard to the National Insurance Bill. The meeting was called by authority of the Scottish Committee of the British Medical Association. The meeting was held in the hall of the Students' Union. Sir William Turner, K.C.B., occupied the chair, and there was a large and representative gathering of members. The chairman, in his opening remarks, spoke of the very critical position in which the profession was placed. He warned them to be careful of the acceptance of principles that were not backed up by clear alterations in the text of the Bill. He hoped the profession would hold together and determine that their profession was not to be lowered in its position and robbed of its rights. The meeting was then addressed by Mr. J. Smith Whitaker, who dealt at length and in detail with the steps the British Medical Association had taken with regard to the Bill. He said that the Government had agreed to the insertion of a clause providing for the establishment of local medical committees who would have power in the determination of the wage-limit in different districts and in the determination of the question of remuneration. As soon as the Bill had passed through the Committee stage the whole question would again be referred to the divisions for their consideration and decision. He very strongly impressed upon his audience that their fate lay in their own hands; if they remained firm and united they could get any terms they liked. All that was required was that they should unitedly decline to take contracts under the Bill whatever its provisions might be. A motion was then submitted by Dr. Gordon of Aberdeen and seconded by Dr. Hamilton of Hawick affirming absolute adherence to the six points of the policy propounded and placed before the profession by the British Medical Association, and appealing to all practitioners in Scotland to support liberally by their subscriptions the insurance defence funds. The motion was carried with acclamation, and the chairman declined to have any discussion. It ought, however, to be stated in this connexion that Mr. Whitaker had spoken for one and three-quarter hours, and that country members and men from a distance had to leave. A motion by Dr. D. J. Mackintosh of Glasgow, seconded by Dr. G. R. Livingston of Dumfries, thanking the Council of the British Medical Association for its labours and declaring confidence therein was also passed.

The Edinburgh and Leith Practitioners' Association.

The annual dinner of this society was held on Oct. 25th, Dr. Alexander James being in the chair. Colonel Sir Joseph Fayrer, the superintendent of the Edinburgh Royal Infirmary, was the guest of the evening. The meeting was well attended.

The Rectorial Election at the University of Edinburgh.

The horseplay which characterises the contest for the Lord Rectorship was not lacking this year, but it seems to have been more circumscribed than usual, owing apparently to the police arrangements.

The Association of School Medical Officers for Scotland.

A general meeting of this association was held in the Royal Infirmary, Edinburgh, on Oct. 21st, Dr. E. T. Roberts, the President, being in the chair. After the election of a number of new members, a demonstration of diseases of the skin was given by Dr. Norman Walker. Many cases of special interest to the school medical inspector were shown, and the demonstration concluded with a practical *résumé* of the present treatment and prevention of ringworm, and a consideration of the question of the admission of cases of ringworm to schools. A hearty vote of thanks was awarded to Dr. Walker. The next general meeting of the association will be held in Glasgow on Nov. 18th.

Complimentary Dinner to Professor MacEwan.

On the occasion of his retirement from the acting staff of

Dundee Royal Infirmary Professor David MacEwan was entertained at dinner by his past house surgeons and his friends of the Forfarshire Medical Association. Dr. Charles Templeman, medical officer of health of Dundee, presided over a company of 60, and in the course of the evening, in felicitous terms, proposed the chief toast. On behalf of the former house surgeons he then conveyed to Professor MacEwan a series of gifts for himself and Mrs. MacEwan in token of the affectionate regard of his late assistants. The professor acknowledged the toast and the gifts in well chosen words.

Oct. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Lord Iveagh's Gift to the Dublin Hospitals.

THE members of the managing committees and medical staffs of the Dublin hospitals met on Oct. 24th in the Royal College of Surgeons to express their gratitude to Viscount Iveagh, K.P., for his recent gift to His Majesty King George V. of £50,000 for distribution to the Dublin hospitals. The large hall of the College was well filled, and Viscount Monck presided. In a resolution adopted with a view to showing, in a special manner, their appreciation of his lordship's generosity, the governing bodies and medical staffs recalled a similar generous gift for Dublin hospitals made by Lord Iveagh to King Edward VII. They assured his lordship that it will be their endeavour so to employ the funds which have been placed by him, through His Majesty, in their hands, that the poor, who seek aid at these hospitals, may derive the greatest possible benefit from the charity.

Dublin Hospitals Tuberculosis Committee.

At a meeting of the Dublin Hospitals Tuberculosis Committee, held in the P. F. Collier Memorial Dispensary on Oct. 27th, a report of the work performed by the committee's three nurses during the past eight months was read. In all 308 cases were attended, 3880 visits being paid. Twenty-eight patients improved so as to be able to return to work; 136 were admitted to various institutions; 52 deaths occurred. Much work was done in the way of disinfection of rooms, distributing sputum flasks, supplying food and paying rent while the head of the family was ill, sending children of tuberculous parents into the country or boarding them out, and sending children to schools or institutions after the parents' death. In 46 families visited more than one person was affected. The average number in each family was six. The average weekly income was 13*s.* 8*d.*, but only 5*s.* when the breadwinner was ill. The report was considered most satisfactory. The Collier Tuberculosis Dispensary will be opened on Nov. 1st, and there will be evening attendances twice a week, the attendance on other days being in the morning.

Cerebro-Spinal Fever in County Roscommon.

A serious outbreak of cerebro-spinal fever has occurred in the Strokestown district of the County Roscommon. Some 30 cases have occurred, and six patients have died. Only children are affected. There was at first some difference of opinion as to the nature of the disease among the medical men in attendance, but Sir J. Acheson MacCullagh, Local Government Board inspector, reports that the disease is undoubtedly cerebro-spinal fever.

Royal Victoria Hospital, Belfast.

At a meeting of the Saturday Street Collecting Committee on Oct. 30th it was announced that the total amount of the street collections this year for the hospital, after deducting working expenses, was £1029, a record amount. From Belfast £820 was received (as against £750 in 1910), and from the country districts £277 (as against £221 in 1910). It is hoped to raise £2000 next year.

The Belfast Natural History and Philosophical Society.

Professor J. A. Lindsay has been elected president of the Natural History and Philosophical Society, in succession to Sir John Byers, who has been president of the society for the past three sessions, and who, at the annual meeting on Oct. 25th, was specially thanked for the work he had done in strengthening the prestige and position of the society. It was during his term of office that the arrangement was completed with the corporation of the city of Belfast by which a new city museum and art gallery is to be erected in that city.

The Water Famine in Ireland.

In Belfast it has been found necessary to restrict the water-supply to seven hours daily. Instructions have been issued to the inhabitants to use as little water as possible for personal ablutions and to use none at all for pavements and shop windows. It is urgently necessary that the Stonyford scheme, referred to in THE LANCET of Oct. 28th, should be carried out, and it is hoped that no opposition on the part of the authorities or the public, and no unreasonable self-seeking on the part of the owners of the required land, will obstruct this course. In Derry, on Oct. 28th, only 5 feet of water remained above the draw-off point in the last available reservoir, and unless a complete change in the weather occurs, with torrents of rain, the entire city will have to depend upon a carted supply or upon wells. No water for manufacturing purposes has been allowed to be used for a week, and but for the discovery of wells all the large shirt factories for which Derry is famous would have been shut down. If the water totally fails from the reservoirs, corporation carts will carry water round at a cost of £100 per diem. So far there has been no disease attributable to the scarcity of water or to inferior water being used. During the past ten days "water diviners" have been reaping a harvest by locating springs for manufactories. At a special meeting of the Rathfriland town commissioners, held on Oct. 26th, a resolution was passed approving of a scheme by which that town, situated at a high level in South Down, is to be supplied with water from a catchment area in Altaggart Mountain (a short distance from Hilltown, six miles from Rathfriland) where there is a stream. The catchment area, shut in by hills and covering 500 acres, is 200 feet above the level of the highest street in Rathfriland. A special report indicated that the water was good and that it was free from risk of pollution, and it comes from a very wet district with an average rainfall of 36 inches. By making an impounding dam or reservoir across the stream constant supply could be ensured.

Scarlet Fever in Belfast.

A serious epidemic of scarlet fever is prevailing in Belfast, the cases coming largely from working-class districts.

Prevalence of Infectious Diseases in Newry District.

At the monthly meeting of the Newry rural council, on Oct. 28th, attention was drawn to the large number of cases of infectious disease notified in the district since the last meeting. Six cases of scarlet fever had been reported at Carrickravady, two of diphtheria in Rathfriland, of which one had died; two cases of scarlet fever in Warrenpoint, one in Edentromley, one at Tamnaharry, and one at Bavan. In Newry there had been an outbreak of typhoid fever, with 15 cases altogether.

Cavan Auxiliary Asylum.

At a meeting of Clones rural council, held on Oct. 26th, a resolution was unanimously passed protesting against the proposal to establish an auxiliary asylum in County Cavan, on the ground that it would impose an increased burden on the ratepayers of both counties. The council called upon the ratepayers of Monaghan and Cavan to do all in their power to insist that the additional accommodation required should be provided at the present Monaghan Asylum, and they also authorised their solicitor to employ counsel to appear at the inquiry to oppose the establishment of an auxiliary asylum in Cavan. At a meeting of the Monaghan urban council, held on Oct. 27th, a very strong resolution was passed unanimously also protesting against the establishment of an auxiliary asylum in Cavan.

Oct. 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Is Tuberculosis Heritable?

THE direct transmission of the bacillus from mother to child during pregnancy has been denied by many scientists, inasmuch as ordinarily bacilli are not found in the blood of the fœtus from a tuberculous mother, either among man or among animals. M. Landouzy, dean of the Faculty of Medicine of Paris, some 30 years ago affirmed this transmission from

mother to child. He has patiently continued his researches since that time, and on Oct. 17th made to the Academy of Medicine a communication of the utmost importance which seems to establish this fact beyond dispute. After rendering female guinea-pigs, rabbits, and dogs tuberculous, both before and during gestation, he found neither bacilli nor characteristic lesions in their fœtuses, either during gestation or after birth. But by killing the fœtuses on their attaining an age of some weeks or months he succeeded, by inoculating healthy guinea-pigs with their organs, in giving rise to indisputable tuberculosis, with the presence of bacilli and characteristic lesions. The failure of the former experiments is understood if we admit that the fœtus already tuberculous at birth presents bacilli in only a very small proportion. But according to Landouzy the bacillus is clearly transmissible from mother to fœtus, and even when it escapes detection various signs of degeneration, such as malformations and dystrophies, are to be found in the offspring.

The Water-Supply of Paris.

M. Colmet-Daage, chief engineer of water-supply and sanitation, gave account of the measures in view to increase the water-supply of Paris at the sitting of the Municipal Council on Oct. 25th. According to his calculations, the city can count next year on 80,000 cubic metres of filtered and sterilised water conveyed through the mains of Saint Maur. It will also be possible to complete the aqueduct of Loing with 20,000 cubic metres from a source in the environs of Nemours; this supply would cost 1,200,000 francs. It would provide for immediate relief, after which the doubling of the capacity of the filter basins at Ivry would give in 1915 an additional 60,000 cubic metres. The sources of the Voulzie, the Durtein, and the Dragon would afford yet another 70,000 metres. But as a sensible increase in the needs of the population, and of the population itself must be anticipated, the Prefect of the Seine and M. Colmet-Daage are taking in hand projects of even greater importance.

The Medical Internes of Toulon.

The six internes of the hospital of Toulon have sent in their resignations. They complain of the rigorous *régime* to which they are submitted by the members of the hospital commission and the physician in chief. They will continue their service, however, for four days, so that the patients shall not be left uncared for.

The Cayor Fly.

On Oct. 25th M. Bouvier presented to the Academy of Sciences a communication by M. Roubaud on the evolution of an African fly, the Cordylobia anthropophaga. It was known that this dangerous larva lives in the skin of man and the domestic animals, in which it gives rise to multiple furuncular tumours having a central orifice; but its mode of penetration thither and its life-history were hitherto unknown. By experiments and observations made in the laboratory of Bammako, the author has demonstrated the following facts: The fly deposits its eggs, about 150, not on the body of the host, but in the earth. After 48 hours the primary larvæ emerge and set about finding a host, being able to exist for ten days without nourishment. They climb along the hairs, and once on the skin they form a tumour wherein they dwell during their transformation into secondary and then tertiary larvæ. In ordinary circumstances the total duration of their evolution does not exceed a week. The European may become infected by the young larvæ, which stick to linen that falls to the ground in the cabins, but he is an unusual host. For the native, who sleeps on the ground, infection is of course much easier.

The French Congress of Medicine.

The twelfth session of the French Congress of Medicine was held at Lyons from Oct. 23rd to the 25th. By a happy inspiration the organisers of the Congress arranged its opening for the jubilee of Professor Lépine, who has just retired at Lyons. His friends, pupils, and admirers met in the amphitheatre in which he has always taught. Professor Roque, his successor, spoke in the name of the old pupils. Then Professor Collet presented to M. Lépine a Jubilee Book, the memoirs in which emanated not only from French but also from foreign scientists. M. Cazeneuve, as a Senator, paid a tribute to the great services rendered to French science by M. Lépine; then M. Landouzy, Dean of the Faculty of Medicine of Paris, Professor Henrijean of Liége, and Professor Joubin, Rector of the University of Lyons, who presided at the ceremony, spoke in succession. Finally, M. Lépine, after expressing his thanks, transferred to his colleagues of the Faculty all the eulogiums that had been pronounced on him for the increasing success of the Lyons school. The first session of the Congress took place in the great amphitheatre of the Faculty of Medicine and was attended by 800 members, presided over by M. Hériot, the Mayor of Lyons. After delivering the opening address the Mayor surrendered the presidential chair to Dr. Chauveau. Diabetes, with its grave complication of coma, first engaged attention. In a discussion on the best diuretics Professor Pic gave a *résumé* of his work on this subject. Professor Widal, Professor Abrami, Professor Chauffard, and M. Nolf discussed icterus due to fragility of the blood cells, which broke up losing their colouring matter and staining the tissues. Dr. Rouget presented a report upon cerebro-spinal meningitis. Finally, arsenobenzol gave rise to numerous discussions. After an acknowledgment of its merits the conclusion was arrived at that it was necessary to distrust solutions made with too stale sterilised water, and it was emphasised that arsenobenzol is a dangerous drug, which must be administered with prudence and reserve if the arteries, the kidneys, and the liver are not in sound condition.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Therapeutic Action of Salvarsan.

THE annual congress of the German Association of Naturalists and Medical Men was this year held in Karlsruhe, when Professor Ehrlich read a paper on salvarsan. In dealing with the question of the alleged dangers connected with its administration, he said that recently every death of a syphilitic patient treated by salvarsan had been indiscriminately attributed to the remedy itself. He mentioned a remarkable instance in which a death at first assigned to this cause was afterwards ascertained to have been a case of murder. Painful induration and subsequent thrombosis of the veins were due to the injected solution having been made too alkaline, so that the walls of the veins were eroded. The troubles of the bladder observed in Prague were caused by a decomposition of the preparation which had been exposed to the air. Undesirable symptoms, such as headache, vomiting, and diarrhœa, had been found to be due to the use of impure water containing bacteria; and in this connexion Professor Ehrlich mentioned experiments carried out by Dr. Jakimoff showing that certain bacteria increased the toxicity of salvarsan. Some patients after an injection showed certain nervous troubles, especially affecting the auditory nerve, the explanation being that when a nerve was enclosed in a narrow channel and a reaction in the form of a swelling of the neurilemma was caused by the salvarsan, a compression of the nerve must necessarily occur, and deafness might result. The symptoms in question might commence either some hours or some days after the injection, according to the accessibility of the nerve. The so-called relapsing disorders of the optic and auditory nerves occurring after intervals varying from three to five months were also caused by their inaccessibility, and not by arsenical poisoning. According to statistics collected by Dr. Benario 194 cases of such relapses after treatment by salvarsan and 122 after treatment by mercury were described in medical literature during the same space of time; these symptoms were therefore not due to arsenical poisoning. A very few deaths have, however, happened during treatment by salvarsan, and in these cases the necropsies showed hæmorrhagic encephalitis, which was observed only after infections and the action of toxic substances. Such mishaps might in future be avoided if patients presenting nervous symptoms were from the beginning treated by small but repeated doses of salvarsan. Absolute rest after the injection was very important. In view of the fact that more than 100,000 injections must have been given the proportion of accidents was comparatively small. The "sterilisatio magna"—the radical cure of a patient by a single injection which destroyed all the disease germs—has been successful in relapsing fever and in frambœsia, the latter being a tropical disease which many have regarded as incurable. Professor Ehrlich mentioned that in a hospital in the Dutch colony of

Surinam injections were given to 328 patients suffering from framboesia, the result being that the last patients could be discharged recovered at the end of a fortnight, and the hospital was accordingly closed. Among 900 cases of framboesia there were only three in which the treatment was unsuccessful. Bilharziosis, Aleppo boil, and glanders have also been completely cured by one injection. In trypanosomiasis and in sleeping sickness salvarsan was unfortunately less efficacious. In the early stage of syphilis—namely, in that of chancre and roseola—there was complete recovery in 90 per cent. of the cases.

Fæcal Accumulation as a Cause of Bronchial Asthma.

Professor Ebstein of Göttingen, writing to the *Deutsche Medizinische Wochenschrift*, has stated that a connexion exists between bronchial asthma and coprostasis. He mentioned the case of a boy of 8 years of age who had been suffering for a long time from bronchial asthma and in whom it was observed that the asthmatic seizures decreased after a stay on the seaside, but subsequently became as frequent as before. Professor Ebstein found the patient's rectum and colon filled with great masses of hardened fæces, which were only removed after repeated enemata of sesame oil, the effect of this treatment being that the asthmatic attacks disappeared for good. Another case was that of a woman, aged 42 years, who had been suffering for several years from dyspepsia and chronic constipation and in whom severe attacks of bronchial asthma developed, which completely disappeared as soon as the coprostasis was relieved. After nine years there was a return of the asthma, and it was then found that constipation was again present. By therapeutic measures the constipation was overcome and the asthma once more disappeared. This was not likely to have been a mere coincidence, because the asthmatic attacks became less frequent as soon as the intestines were evacuated. Professor Ebstein is of opinion that bronchial asthma was in these cases caused by the absorption of toxins from the contents of the intestines. The nature of these toxins has not yet been ascertained, but it was advisable that in every case of bronchial asthma the state of the intestines should receive attention, and if there was fæcal accumulation, appropriate treatment should be resorted to.

Acromegaly Caused by Fright.

Professor Pel of Amsterdam has published in the *Medizinische Klinik* two cases in which acromegaly developed after a fright. Both the patients were females, one of them, aged 25 years, having been terrified by an explosion of gas, and the other, aged 26 years, by an outbreak of fire. In both cases the first symptom was amenorrhœa, which was in course of time followed by acromegaly. Radiography showed that the sella turcica was enlarged, but symptoms of cerebral pressure were present in only one patient. Together with an instance described previously by the same author, there are now on record three cases in which the disease has been the sequel of a violent psychical impression, so that a mere coincidence is rather unlikely. Professor Pel, after remarking that Graves's disease was well known to be caused by impairment of the function of the thyroid gland, and that diabetes might depend on disordered action of the pancreas, said that the hypophysis belonged, like the pancreas and the thyroid gland, to the class of ductless glands or glands with internal secretion.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Medico-Military Service.

THE silent celerity with which the Italian War Office organised the expedition for the annexation of the Tripolitania has evoked the admiration of foreign Powers, to whom, indeed, the fact has come with something of a surprise. When to this is added the completeness and the efficacy of the equipment, down to the minutest detail, the admiration and the surprise are equally enhanced, remembering, as the said Powers must do, the celerity without silence and the equipment, far from efficacious, with which Italy's campaign in Abyssinia closed in the disaster of Adowa. But the lesson of 1896 has borne salutary fruit in 1911, and the Italian War Office of the latter year is as superior to that of the former as the generalship of Caneva is to that of Barattieri. In no department of the present enterprise is the superiority in question more conspicuous than in the army medical service, up-to-date as it is in every particular, and inspired with a forethought and a thoroughness of good augury. Hospital service, whether stationary or mobile, "sections" of surgical or medical relief (*sezioni di sanità*), down to tents improvised for treatment in either sense—all are in evidence within and without the area of fire, with a completeness and an efficiency quite novel in Italy's medico-military record, and excelled by few, if any, of her sister Powers. Every unit of the service is provided with acetylene searchlights supplementary to those of the combatant force for seeking out the wounded. Nor is the commissariat one whit below the standard of medical requirements. No campaign has yet failed to inculcate the lesson that while its dead and wounded are infinitely fewer than its ailing and invalided, the chief cause of these latter is the defective or positively deleterious nutriment served out to the soldier, condemned, as he often is, to wait for long hours spent under fire or on the march, in expectation of food, bad in itself and worse cooked. This source of suffering has been minimised, not to say annulled, by the provision now made for the refection of the expeditionary force, portable cooking apparatus of the best type and yielding the best results being now in operation, most of it, moreover, of Italian invention and construction. Keeping in immediate touch with the troops, this apparatus supplies the force after a march of 16 miles with a warm meal, as palatable as it is sustaining and restorative, to the great comfort and exhilaration of the soldier. Special care has been bestowed on the bread, which, thanks to the acetylene illumination, can be prepared at night, so as to be fresh, crisp, and appetising at the morning meal. If, as now seems possible, we must not count on a speedy issue of the campaign, the responsibilities of the medico-military service may become very heavy, and it is well to know that the service appears to be ready to meet all calls.

The International Monument to Cesare Lombroso.

While cordially approving of the tribute about to be paid by international coöperation to the founder of "Criminal Anthropology," Professor Hans Evensen, director of the Criminal Asylum at Drontheim, in a lecture delivered there and just published at Christiania, does not see eye to eye with Italians in their estimate of the man and his work. Crediting Lombroso's theory of the genesis of pellagra with little more than a stimulating value for the better inspired researches of Terni, Sambon, and Alessandrini, Professor Evensen enlarges on the merit of his work in connecting crime with atavism and epilepsy, and holds that, if Lombroso's type of delinquent has never been fully accepted, the great majority of experts are in accord with him as to the existence of the "delinquente nato" or "criminel né"—the individual, to wit, who from infancy is devoid of the capacity of harmonising his conduct with moral criteria, owing to his brain being insufficiently developed or deteriorated through lesions operative before birth. Even in very favourable circumstances, such an individual (says the Norwegian criminologist) will be found to transgress the laws imposed by society for its own protection. Professor Evensen, in his estimate of Lombroso's best-known publication—that on genius and madness—traces its defects to the fact that the author too often accepted his data on trust without personally examining and testing them. Lombroso, moreover, in resolving into epilepsy whatever is pathologically abnormal in the mental growth of the human subject exceeds the bounds of legitimate induction, the fact being (according to Evensen) that epilepsy has no preponderating part in delinquency, still less in the development of "genius." The great and indisputable merit of the Italian criminologist lies in his having been the pioneer of research in the "frontier regions" of his science—virgin soil which he was the first to cultivate, overrun as it was, and still is, by weeds of every kind. "Few works of our century," says Professor Evensen, "have wrought so many reforms as that on the 'Uomo Delinquente.'" Lombroso's powerful imagination sometimes ran away with him, giving form to theories often unsubstantiated by fact. But even such imagination as his has its indefeasible value, speculation and intuition being factors with which science can never dispense.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Hygiene of Tobacco-smoking.

IN a paper on tobacco-smoking published in a recent number of the *Orvosok Lapja* Dr. Pekanovics described some of the injurious effects of this practice. He said that besides nicotine, tobacco-smoke contained nicotianine, collidine, and other pyridine derivatives, acids, resins, carbon dioxide, hydrocyanic acid, and ammoniacal salts. Two drops of nicotine placed on a dog's tongue produced in succession efforts to swallow, great weakness, convulsions, and death in less than a minute; eight drops of it were sufficient to kill a horse. Tobacco contained from 2 to 8 per cent. of nicotine, and M. Le Bon, a French observer, has determined that though most of this was changed in smoking it was converted into other pyridine bodies which were just as poisonous. Dr. Pekanovics found that these bodies did not condense to any great extent in the warm mouth, and were mostly exhaled, so that the physiological effect of ordinary smoking was not very marked. Susceptible persons might, however, be much affected by breathing the air of a room in which there was much tobacco-smoke. The action of nicotine had been shown by the investigations of Petit to be intermediate between that of the bromides and of digitalis. It soothed the nervous system, but caused a powerful and rapid contraction of the vessels and a rise in blood-pressure. Among its dangers, therefore, one of the best known was angina pectoris, perhaps due to spasm of the coronary arteries. Through prolonged use it promoted the development of arterio-sclerosis. Tobacco was a "habit-drug," like opium, cocaine, and alcohol, and its devotee lost the force of will necessary to stop the habit, though he knew it was harming him. Tobacco-smoke had apparently no bactericidal action on any micro-organisms present in the lungs. One of the first effects of an overdose was nausea, and prolonged smoking was a distinct factor in the production of digestive troubles.

Short-sightedness in School Children.

Dr. Bogdan has given in the *Orovsok Lapja* an account of his examination of 200 school text-books from a sanitary point of view. He has here drawn particular attention to the fact, already established by many prominent investigators, that short-sightedness in children either originated or developed in connexion with school education. The chief causative agency was, in fact, to be found in too prolonged reading, writing, and drawing, whereby visual accommodation as well as convergence were greatly fatigued. Undue strain of the muscles of accommodation caused an active hyperæmia; the return flow of the venous circulation was greatly hindered, there was an increase of the intra-ocular pressure, and the sclerotic was gradually stretched. Too strong convergence worked even greater harm for the eye in various ways. It must also be observed that in some of the children short-sightedness was hereditary, and they became affected much sooner than their healthy comrades. In addition to the above causes producing short-sightedness, mention must be made of insufficient admission of light in many schools; a similar remark applied to unsuitable desks and other school furniture. As regards the influence of books on the eyesight, Dr. Bogdan insisted that paper should not have a glossy surface, for under artificial light a surface of this kind prevented the eye from seeing well and necessitated moving the book to and fro, as well as frequent changes in the position of the head. Again, the paper should be thick enough to prevent the printing of the next page from obtruding itself upon the reader's eye. A few authorities have recommended yellow paper, but the majority were in favour of white paper, which gave a better contrast between the printed matter and the background.

A Case of Rhinophyma.

An interesting case of this rather rare condition, in which operation was followed by remarkably good results, was reported by Dr. Imre Fischer at a meeting of the Nagyvárad Medical Society on Oct. 1st. The patient was a man aged 65 years. There was no history of injury. Some years ago he had what was probably an attack of acne rosacea in which the nose and the adjacent borders of the cheeks were most prominently affected. This was followed by a nodular growth of the nose which involved all of that organ except the upper fourth. The growth gave rise to no pain. Breathing was not interfered with, but the projecting mass caused much difficulty in eating. The operation consisted in the making of an elliptical incision with removal of the enclosed part followed by shaving of the growth on each side. Contrary to expectation there was very little hæmorrhage. The cosmetic result was very good, an interesting point being that over the area where the growth was simply shaved off skin of normal appearance has been reproduced instead of scar tissue; this was chiefly due to the fact that after the removal of the growth the whole surface was touched with a pencil of carbonic acid snow. Histological examination of the removed tissue showed it to be a soft fibroma of the skin with conspicuous distension and possibly hyperplasia of the sebaceous glands.

Treatment of Epilepsy.

Dr. Rene Berkovics recommends the double bromide of rubidium and ammonium in the treatment of epilepsy; he has seen decidedly better results with this salt than with other bromides. The action is in the main the same, since the rubidium does not exercise any specific effect. The daily dose is 4 to 7 grammes; 4 or 5 grammes given at night are an excellent hypnotic.

Oct. 28th.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Libel Action against General Hertzog.

Dr. A. B. Ward, President of the Medical and Pharmacy Council of the Orange Free State, has instituted legal proceedings for alleged slander against General Hertzog, Minister of Justice. He is claiming £1000 as damages. The case arises out of speeches made by General Hertzog at Smithfield and Fauresmith last year during his electioneering campaign, when he attacked the Medical and Pharmacy Council in connexion with its action in refusing to issue licences to practise to two young medical men holding the certificates of the German Staats Examen, in accordance with a ruling furnished by the Council's legal adviser. The plaintiff in the action avers that the words used by defendant mean that plaintiff, in conjunction with certain other members of the Council, acting in their official capacity, had adopted a biassed, unjust, and discreditable attitude, and had generally abused the position and powers conferred upon them by the law. It is expected that the case will be heard during the November term in the Provincial Division of the Supreme Court at Bloemfontein. This is the second libel action which has been taken against General Hertzog in connexion with his electioneering campaign, the first having already been taken by an inspector of schools who had been dismissed by General Hertzog when Minister of Education in the Orange River Colony. Dr. Ward and his colleagues on the council, after the alleged slander was published, endeavoured to elicit from General Smuts, the Minister of the Interior, a statement that he, as the responsible Minister, was satisfied that the council had acted rightly, and on failing to get a satisfactory answer from the Minister and subsequently from the Cabinet resigned their positions on the council. All the elected members who resigned were, however, re-elected to the council by large majorities, and Dr. Ward was again elected president by the council. He has thus been vindicated by the profession, and it remains to be seen how he fares in the law courts.

Monthly Meeting of Chamber of Mines.

At the last monthly meeting of the Chamber of Mines Mr. H. Webber, the President, made a most interesting speech which indicates that the chamber intends taking active measures in endeavouring to reduce the appalling mortality occurring amongst native mine labourers. The President, *inter alia*, alluded to a research now being undertaken by Dr. Macaulay on behalf of the chamber into the quality of the mealie meal and rice supplied to natives on the gold-fields, and stated that the results so far obtained showed that in a number of samples analysed some of the most important food constituents of the grain appear to be eliminated as waste in the course of grinding and preparation, and that it has been ascertained that these are sold separately as food for cattle. This may possibly prove of some importance in connexion with the prevention of scurvy. Mr. Webber also expressed the hope that the engagement of Sir Almroth Wright for the purpose of carrying out an investigation into the question of

immunisation against epidemic pneumonia might result in the disease being eradicated from the native compounds, where for so many years it has been so terribly prevalent. He also announced that the medical officer for the Witwatersrand Native Labour Association had been sent during the year to investigate sleeping sickness, more particularly in order to ascertain what probability there was of the disease being introduced into South Africa by means of labourers recruited for the mines from the north. He stated that Dr. G. A. Turner, the medical officer referred to, had just returned and had reported quite definitely that there was no danger whatever of the disease ever breaking out in the rand compounds even if introduced from outside.

Farewell Dinner to a Practitioner.

Dr. W. Watkins-Pitchford, who has been transferred to Johannesburg, was entertained before he left at a farewell dinner.

The Need for Public Slaughter-houses in South Africa.

The conditions under which animals are slaughtered for food in most South African towns are very unsatisfactory. The majority of local authorities appear to be of the opinion that as long as the animals are killed out of the public view, and the meat exposed for sale in reasonably clean premises, nothing else matters. Accordingly the slaughter-houses in use are generally insanitary and filthy, and without a water-supply and proper drainage, whilst those engaged in slaughtering are generally dirty in their persons and clothing. In connexion with most slaughter-houses there are a number of natives employed, and it is not uncommon to find amongst these some afflicted with syphilis, tuberculosis, or some other prevalent disease. The meat is conveyed to the shops in wheelbarrows or wagons, exposed to sun and dust, or else merely covered with a dirty tarpaulin. In a few but happily in an increasing number of urban areas the public meat-supply is under proper supervision. Thus the enterprise of the Johannesburg Town Council has resulted in the erection of a large public slaughter-house which supplies meat slaughtered under supervision not only to the inhabitants of the town, but also to a considerable extent those of the other mining towns along the Reef. Bloemfontein also has its public slaughter-house. Durban is understood to be contemplating the same, although this area is equipped with fairly good private slaughter-houses which are worked under close municipal supervision. In the Cape Peninsula municipalities it is stated that a most revolting state of affairs exists, owing to the fact that the owners of private slaughter-houses have been for some years under notice to cease slaughtering in the same. The operation of the closing orders has apparently from time to time been suspended, while the various municipalities have been negotiating amongst each other for the erection of one or more joint public slaughter-houses. These negotiations have been going on for a period of six or seven years, the difficulty being that the municipalities could not come to an agreement as to a site. It is understood that this difficulty has at last been solved, and that the ratepayers of the respective municipalities have sanctioned an expenditure of £35,000 for the purpose of erecting a slaughter-house under joint control. In view of the population to be served, it is understood that the municipal experts are very doubtful if adequate premises can be erected for such a small sum. However, the buildings can always be extended if this proves to be needed, and the closure of the existing slaughter-houses should now be possible within the course of the next few months.

Oct. 2nd.

Obituary.

STANLEY SMITH, M.D. DURH., M.R.C.P. LOND.

WE regret to announce the death of Dr. Stanley Smith, which took place at his residence, Wimpole-street, Cavendish-square, on Oct. 25th, in the sixtieth year of his age. Dr. Stanley Smith received his medical education at London Hospital, and after taking the Membership of the Royal College of Surgeons in 1877 was for a short time house physician to the hospital from which he had qualified. In 1882 he took the L.R.C.P. and L.M. diplomas of Edinburgh, and in 1895 became a Member of the Royal College of Physicians of London and a Doctor of Medicine of the University of Durham. He was physician to the Railway Clearing System Superannuation Fund Corporation. His contributions to medical literature included Empyema: Simple Drainage with Antiseptic Precautions, which was published in THE LANCET in 1882, and Notes on the Treatment of Diphtheria, published in the *British Medical Journal* in 1887.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Oskar Wilhelm Aschenborn, medical adviser to the Prussian Ministry of the Interior. He formerly held various honorary appointments in connexion with the medical associations. His age was 60.—Dr. Julius Caspary, emeritus professor of dermatology in the University of Königsberg. He edited formerly the *Archiv für Dermatologie und Syphilis*, and contributed to Eulenburg and Samuel's great text-book. He was 75 years of age.—Dr. Piettre, member of the French Senate.—Dr. Henry Gibbons, professor of midwifery and gynæcology in Cooper Medical College, San Francisco.—Dr. J. A. Wilder, professor of pathology in the Denver and Gross College of Medicine.

THE REAPPEARANCE OF PLAGUE IN SUFFOLK.

PLAGUE bacilli have been found in the sputum of a seaman who was admitted on Oct. 10th into the sick quarters of the Naval Barracks at Shotley, in Suffolk, apparently suffering from pneumonia. The patient was isolated as soon as suspicions were aroused of the true nature of his complaint. No other cases have been reported, and it appears from an official communication from the Local Government Board that the origin of the infection is not known.

Thus it would seem that a case of pneumonic plague has arisen this autumn in the same corner of East Suffolk in which various cases of supposed human plague were reported about a year ago, and in which plague-infected rats were undoubtedly then present in considerable numbers. The subject of plague in rats and man, with special reference to the Suffolk epizootic of rat plague and the risks of human plague in England, has been dealt with in detail in various recent issues of THE LANCET.[1] In these articles we have traced the history of the East Anglian cases and of previous outbreaks in this country, and have discussed the special circumstances which are likely to affect the appearance and spread of plague at home, and have outlined the measures which should be taken to avert an epidemic of this disease in the event of further cases arising.

The present case of pneumonic plague on the bank of the river Orwell should of course give rise to searching inquiry and the most vigorous precautions, for the pneumonic type of the disease, which is by far the less common, is also by far the more infectious in human beings. Because there have been but few cases of plague in this country for so many years it does not follow that we can afford to relax our guard; and, indeed, the lesson of history shows that such a course invites disaster. But there is no justification for a scare. The present high state of efficiency in sanitary administration and the improved standard of domestic cleanliness in this country must prove strong factors in the limitation and control of plague, as was shown by the experience of Glasgow in 1901. The personal conditions which favour the spread of such a disease among the ignorant natives of India are almost non-existent in this country. Moreover, the Norwegian rat, which has exterminated the black rat in this country, is not primarily a house rat, but a dweller in sewers, docks, and barns, while the British rat-flea, unlike the Indian variety, has little or no taste for human blood. It seems probable that the prompt notification and isolation of all doubtful cases, together with accommodation for keeping contacts apart and under observation, and facilities for preventive inoculation, provided they are associated with wholesale systematic rat destruction in infected areas, would amply safeguard the inhabitants of these islands against anything like a serious epidemic of plague. If rats can be kept outside houses the risk of human plague infection becomes very small.

[1] THE LANCET, Nov. 5th, 1910, p. 1353; Nov. 19th, 1910, p. 1497; Dec. 31st, 1910, p. 1903; and Sept. 2nd, 1911, p. 697.

THE RESEARCH DEFENCE SOCIETY AND ANTI-VIVISECTION SHOPS.

WE have received the following important letter from the officials of the Research Defence Society, whose action in distributing widely their vigorous appeal will receive general commendation :—

SIR,—We desire to make a special appeal, for the purpose of undoing the harm which is done by anti-vivisection shops and processions. The exhibits in these shops are of a most misleading nature; and the truth as to anæsthetics is carefully concealed. No operation, more than the lancing of a vein just under the skin, is allowed to be done on any animal in this country, unless the animal is under an anæsthetic throughout the whole of the operation.

It will be remembered that one of these shops, on the death of H.M. King Edward VII., distributed a leaflet suggesting that His Majesty's death was due to medical treatment.

We have, of course, received many complaints against these shops. We find that the police have no power to close them: and we can only place men outside them, to give our leaflets to passers-by.

But this constant giving of literature is a heavy expense to our society. We therefore appeal for special contributions toward this purpose. We make this appeal with confidence, for we are sure that the public recognises the grave harm which is done by these shops, especially to children. All contributions should be sent to the hon. treasurer, Research Defence Society, 21, Ladbroke-square, London, W.

We may, perhaps, take this opportunity of mentioning that a letter has just been received from Sir Apolo Kagwa, K.C.M.G., the Prime Minister of Uganda. It is dated from Mengo, Uganda, Sept. 26th. "I really think," he says, "that in a few years' time sleeping sickness will be extinct in Uganda, and people will become immune from the disease." If this happy result is obtained, it will, without doubt, be due to the work done by the Royal Society Commission, who gained their knowledge on the subject by experimentation on animals.

We remain, yours faithfully,

CROMER, President.
SYDNEY HOLLAND, Chairman of Committee.
F. M. SANDWITH, Hon. Treasurer.
STEPHEN PAGET, Hon. Secretary.

21, Ladbroke-square, London, W., Nov. 1st, 1911.

THE ROYAL SANITARY INSTITUTE.—A sessional meeting of the Royal Sanitary Institute will be held at 90, Buckingham Palace-road, on Nov. 14th, when a paper will be read on "Sewage Farms," by Mr. H. A. Roechling, M.Inst.C.E. Among those who have promised to take part in the discussion are: Professor A. Bostock Hill, Professor Henry R. Kenwood, Dr. George Reid, and Dr. S. Rideal, D.Sc. The chair will be taken at 8 P.M. by Mr. H. Percy Boulnois, M.Inst.C.E., and a general discussion will be invited. Tickets for admission of visitors may be had on application to the secretary at the institute.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce for early publication the second edition of "A Short Practice of Medicine," by Dr. R. A. Fleming, in which considerable additions and alterations have been made; the second edition of "Essentials of Surface Anatomy," by Charles R. Whittaker, of which a new feature is the introduction of 12 coloured plates; "The Tobacco Habit, its History and Pathology: a Study in Birth-rates: Smokers compared with Non-smokers," by Dr. H. H. Tidswell; and "Cocoa and Chocolate: its Chemistry and Manufacture," by R. Whymper.—Messrs. Baillière, Tindall, and Cox announce that they have been authorised by the Department of Education of the Sudan Government to publish the Fourth Report of the Wellcome Tropical Research Laboratories, Khartoum. The third report was issued in 1908. The fourth report is in three volumes. Volume A, Medical, represents the research and routine work of the bacteriological section, together with papers on the work of Sleeping Sickness and Kala-azar Commissions; Volume B deals with General Science; and Volume C consists of a second review of Some Recent Advances in Tropical Medicine.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Wilhelm Ceelen has been appointed Prosector of the Pathological Institute of the University in succession to Dr. Beitzke, who is migrating to Switzerland. Dr. Oskar Rumpel, *privat-docent* of Surgery, has been granted the title of Professor. Dr. Adolf Magnus-Levy, whose researches on the pathology of metabolism have attracted much attention, has been appointed Director of the medical side of the Friedrichshain Hospital in succession to the late Dr. Krönig. —*Breslau:* Dr. Julius Strasburger, of the Bonn Policlinic, has been offered the Directorship of the Policlinic with an Extraordinary Professorship, in succession to the late Dr. Richard Stern.—*Cagliari:* Dr. A. Gentili has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Catania:* Dr. F. Pulvirenti of Rome has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Florence:* Dr. P. Rondoni has been recognised as *privat-docent* of General Pathology; Dr. Ugolotti as *privat-docent* of Neurology and Psychology; Dr. F. Leoncini as *privat-docent* of Forensic Medicine; Dr. A. Rossi as *privat-docent* of Surgery and Operative Medicine; and Dr. I. Cappelli and Dr. M. Nencioni as *privat-docenten* of Dermatology and Syphiligraphy.—*Genoa:* Dr. A. Maggione has been recognised as *privat-docent* of Odontology.—*Göttingen:* Dr. Stich of Bonn has been appointed to the chair of Surgery in succession to the late Dr. Braun.—*Königsberg:* Dr. P. L. Friedrich of Marburg has been appointed Professor of Clinical Surgery in succession to Dr. Payr. Dr. Martin Hahn of Munich has been offered the chair of Hygiene.—*Lausanne:* Dr. Beitzke of Berlin has been appointed to the chair of Pathological Anatomy in succession to the late Dr. Stilling.—*Naples:* Dr. F. Galdi has been recognised as *privat-docent* of Medicine.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Oct. 20th. There were present: Dr. F. de Havilland Hall (in the chair), Dr. J. Pickett, Dr. A. C. Hartley (Bedford), Dr. M. G. Biggs, Dr. F. C. Martley, Mr. F. S. Edwards, Dr. St. Clair B. Shadwell, Mr. J. Brindley-James, Dr. F. J. Allan, Dr. Frederick S. Palmer, Mr. H. P. Symonds (Oxford), Dr. M. Greenwood, Dr. R. Hutchison, and Dr. J. B. Ball. The accounts presented showed that the business for 1911 has so far been very good. A considerable margin has been secured in the sickness claims and also in the interest earned by the funds, while the management charges have been well under the amount allowed by the rules. The financial result therefore is very satisfactory, and the funds, now amounting to about a quarter of a million sterling, are still rapidly growing and are ample to provide for all claims that may arise. Prospectuses and all further particulars may be obtained on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

DONATIONS AND BEQUESTS.—The late Countess Dowager of Seafield has left the following legacies: £1000 to the Infirmary, Inverness; £1000 to the Chalmers' Hospital, Banff; £18,000 to the trustees on behalf of the Ian Charles Cottage Hospital, Grantown, the income of which is to be applied towards the maintenance and upkeep of the hospital, and the necessary expenses connected therewith, any surplus to be accumulated and to be available for the expenses thereof in subsequent years. The testatrix empowers the trustees (should they think it necessary) to enlarge and extend the building, and for that purpose to use the savings of income from the endowment of £18,000 under her last will and testament. Should the trustees find it necessary to acquire more land on behalf of the hospital, she desires the proprietors of the Strathspey estates for the time to give such land free from all charge, or for a nominal feu duty.—The honorary secretaries of King Edward's Hospital Fund for London have received £500, the current year's instalment of the £2500 voted by the Corporation of the City of London. —The late Mr. David Fenby has bequeathed £500 each, free from duty, to the Sheffield Royal Infirmary, the Sheffield Royal Hospital, the Jessop Hospital for Women, and the Crookes Orphan Homes.

TURIN EXHIBITION AWARDS.—Messrs. Burroughs, Wellcome, and Co. have secured 13 awards—eight grand prizes, two diplomas of honour, and three gold medals—for their exhibits at the Turin International Exhibition. This probably constitutes a world's record in awards received by a single firm at an exhibition open to all nations.

A PROPOSED IMPERIAL HOSPITAL AND NURSING HOME.—The demand for private nursing homes by a large number of the better class and well-to-do patients coming from the provinces and from the overseas Dominions is very great, while the accommodation provided does not adequately meet that demand. In many cases patients have no choice between a charity and a home which is not subject to medical supervision and where charges are often prohibitive. Patients may have thus a difficulty in selecting an institution suitable to their needs. In these circumstances the proposal to build a large hospital or nursing home can be justified if it is found that the scheme can be carried out in a manner likely to benefit the public at large, while leaving that public at liberty to be attended by medical men of their own choice. It is proposed that a building, for which the necessary capital of £18,000 has already been subscribed, shall be erected in Vincent-square, Westminster, and that in the first instance accommodation shall be provided for 40 beds. The management of the hospital is to be chiefly in the hands of medical men elected by a board of directors, and the charges, which will range from three guineas upwards, will be quite apart from those for professional attendance.

NATIONAL ASSOCIATION FOR THE AFTER-CARE OF THE FEEBLE-MINDED.—A meeting of this association was held at Brighton on Oct. 27th and was attended by a large number of delegates from various parts of the country. The conference agreed to place on record the fact that it had passed the following resolution:—

That this conference emphatically expresses its belief that the time has arrived when the Government should pass a Bill making permanent segregation of the feeble-minded compulsory, and urges the immediate preparation and passage of such a measure.

The conference was not quite unanimous in this resolution, but those delegates holding the view that no further powers should be given to local authorities to detain feeble-minded persons until suitable colonies have been provided were considerably in the minority. Sir William Chance, as chairman of the association, presented the after-care report and statistics for 1911, showing that the total number of cases dealt with was 3283, an increase of 527 over the previous year, and three times as many as the total number of cases under observation five years ago. The proportion of cases reported upon as doing remunerative work was 19 5 per cent. There were only 202 cases reported upon as useful at home, 28·6 were reported upon as absolutely useless to society, and 14·1 per cent. as in asylums, workhouses, or other institutions, while the number of cases lost sight of had increased from 19 to 23 per cent. for the total number of cases. 612 were those of children under the age of 14. Sir William Chance strongly urged compulsory registration and supervision of all cases of mental defect, and said the returns showed how necessary it was for the Government to take the matter boldly in hand as soon as possible and deal with it in a thoroughly scientific manner, not ousting voluntary efforts altogether but enabling them to produce better results, and rescuing, by the institution of permanent care, the many unfortunate persons who, without such care, continued to be a danger not only to themselves but to the whole community. Delegates enlarged upon the pressing need of colonies in which to segregate patients; and the case of a Brighton institution was mentioned where 50 boys and girls were being excellently brought up, but at the age of 16 had to leave and go into the streets and byways and find their own living, which they found to be an impossible task. A note of warning was sounded by a clerical delegate who held that as regards the provision of segregation colonies economy might be preached to architects. Papers were read by Dr. Helen Boyle on Methods of Dealing with Feeble-minded Cases Bordering on Lunacy; Dr. R. J. Ryle on the Origin of Feeble-mindedness; Dr. R. D. Clarkson on Scotch Methods (read by Sir William Chance in the absence of Dr. Clarkson); Dr. Isabelle Thompson Smart of New York, on American Methods (read by Dr. Potts in the absence of Dr. Smart); Dr. G. E. Shuttleworth on the Egyptian Institution; and by Dr. Alice Vowe Johnson describing Visits to the Ursberg Colony in Bavaria and the Working of the Gheel System in Belgium. All the papers were most instructive, and the conclusion arrived at in each of them was that the great object to be attained by the after-care of the feeble-minded was to render the subject a self-supporting citizen.

SHIPS' SURGEONS: A NEW DEPARTURE IN THE PENINSULAR AND ORIENTAL COMPANY.—The Peninsular and Oriental Company has instituted a new departure with reference to its surgeons. Beginning on Jan. 1st, 1912, surgeons in the service of the company will be allowed to charge a fixed fee for each consultation with first- and second-class passengers. The pay, £10 per month, remains as before.

Dr. Joseph Francis Dixon has been appointed medical superintendent of the Borough Asylum, Leicester.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

UNDER the "guillotine" resolution the National Insurance Bill is passing rapidly through Committee in the House of Commons, but it is not expected to reach the House of Lords until the beginning of December. Last week the discussions on the Bill referred to the conditions which societies must fulfil in order to become approved societies. The chief alteration made was the excision of the condition that approved societies must have at least 10,000 members being insured persons. This change was made at the instance of the CHANCELLOR of the EXCHEQUER, who has drafted a new clause to provide for the grouping of small societies with less than 5000 insured members. An interesting discussion arose on an amendment brought forward by Mr. GILL on behalf of the Labour Party. It was to the effect that the rules of an approved society "must not provide for medical tests as a condition of membership under this Act." The honourable Member contended that if Friendly Societies had the right to select lives they would select only the best and those which did not reach that standard would have to go into the Post Office as deposit contributors. Mr. GILL urged that by admitting good and indifferent lives, an average would be obtained, and as all had to pay alike, the risk should be taken by all the societies on an average basis. Mr. MASTERMAN, on behalf of the Government, declined to accept the amendment, on the ground that it was impracticable in application and distasteful to the Friendly Societies to compel them to take people without a medical test. Mr. BARNES pointed out that trade unions did not impose medical tests, although some of them paid sickness benefits. The result of the clause would be that the bad lives would go to the trade unions and the good lives to the Friendly Societies. Mr. RAMSAY MACDONALD elaborated this point, but the CHANCELLOR of the EXCHEQUER maintained that the Friendly Societies must have a control over the persons whom they admitted as members. The amendment was ultimately negatived without a division.

In the early days of this week the House of Commons considered clauses of the National Insurance Bill dealing with the membership of approved societies, surpluses, deficits, and deposit contributors. A very interesting debate arose on the subject of deposit contributors and on the problem of dealing with persons who for reasons of health would not be accepted as members by the approved societies.

As the result of the debate on the question of the Post Office contributors, Mr. LLOYD GEORGE accepted an amendment brought forward by Mr. SHERWELL to the effect that the scheme in relation to them should only be provisional. It was only to have effect until Jan. 1st, 1915. In the meantime other measures would have to be devised. The amendment was carried.

The Health of the Navy.

The statistical report of the health of the Navy for the year 1910 is issued as a Blue-book. In it it is stated that the returns for the year 1910 show a continuous improvement in the general health of the fleet as compared with the preceding five years.

HOUSE OF COMMONS.

TUESDAY, OCT. 24TH.

Milk and Dairies Bill.

Mr. C. BATHURST asked the President of the Local Government Board when he proposed to introduce his long-promised Milk and Dairies Bill.—Mr. BURNS replied: I am afraid that the Government programme for the autumn session will not admit of the passing of the Milk and Dairies Bill this year.

Mr. C. BATHURST: May I ask the right honourable gentleman whether he proposes to introduce this measure in the early part of next session?—Mr. BURNS: Sufficient unto the day is the goodness thereof.

Mr. WATT: Will the Bill apply to Scotland?—Mr. BURNS: No, sir.

WEDNESDAY, OCT. 25TH.

The Nutritive Value of Bread.

Mr. C. BATHURST asked the President of the Local Government Board whether he had taken any administrative, or proposed to take any legislative, action in consequence of the reports of Dr. J. M. Hamill and Dr. Monier-Williams presented to his department in reference to the adulteration of baking-powders and self-raising flour, the bleaching of flour, the addition of so-called improvers to flour, and the respective nutritive values of breads made from the different constituents of the wheat grain in varying proportions.—Mr. BURNS answered: The matters referred to are still under consideration.

Mr. C. BATHURST: How long are they likely to remain under consideration?—Mr. BURNS: The honourable Member must know, and should know, that since the two reports to which he refers in his question were issued I have had to see a number of important deputations, and I have still to see two more on the subject.

MONDAY, OCT. 30TH.

The Sale of Milk.

Mr. BARNSTON asked the President of the Board of Agriculture whether he was now in a position to state the result of the inquiries which the Board had been making as to the manner in which the existing provisions of the law relating to the sale of milk were at present administered by local authorities.—Mr. RUNCIMAN replied: The inquiry is not yet completed. I am afraid that I cannot state when I shall be able to make a general statement on this subject. The work is being carried out by inspectors who have other duties to discharge as well. I understand that they are proceeding with all possible speed. I will, however, look into the matter.

National Insurance Bill Topics.

Mr. BARNES asked the Secretary to the Treasury whether dental attention, including the supply of artificial teeth, would be allowed as medical benefit if a medical attendant under the National Insurance Bill certified that illness arose from septic teeth and gums, and that he, the medical attendant, could not do anything further for the insured person unless his teeth were properly attended to; and would a company which had been proved to have been guilty of fraud be allowed to establish an approved society.—Mr. MCKINNON WOOD answered: With regard to the first part of the question, the matter will be one for the decision of the Local Health Committee, subject to the regulations of the Insurance Commissioners. With regard to the second, the Insurance Commissioners may on sufficient grounds withhold or withdraw approval from a society or separate section of a society.

Mr. CATHCART WASON asked the right honourable gentleman to state what provision there was in the National Insurance Bill for deposit contributors in the Highlands and Islands living at great distances from any medical officer receiving adequate consideration.—Mr. MCKINNON WOOD replied: The Local Health Committees on which the deposit contributors will be represented will be responsible for providing the benefits to which the deposit contributors are entitled. The proviso to Sub-clause (2) of Clause 32 was specially inserted to enable the local committees to deal with deposit contributors separately in such cases.

Mr. KELLAWAY asked the right honourable gentleman whether he was aware that the Pharmaceutical Society of Great Britain did not recognise the pharmaceutical certificates of any British Colony; and if, under the National Insurance Bill, the holders of British-Colonial pharmaceutical certificates who were in business as chemists in this country would be prohibited from supplying drugs and medicines under the Bill.—Mr. MCKINNON WOOD said in reply: I understand that the Council of the Pharmaceutical Society of Great Britain is now engaged in negotiations with the Colonial representatives. It is hoped that it may prove possible to formulate a by-law providing for the admission to the Register of Chemists of persons holding Colonial certificates of qualification equivalent to the British qualification.

Mr. KELLAWAY: Is it hoped to conclude the negotiations in time to make it possible for them to apply under the National Insurance Bill?—Mr. MCKINNON WOOD: I am not able to reply to that question.

TUESDAY, OCT. 31ST.

The Plague in India.

Mr. KEIR HARDIE asked the Under Secretary of State for India whether he could give any information concerning the progress of the plague in India, including the number of fatal cases during the past three months.—Mr. MONTAGU answered: The mortality from plague during the last three months in British India and Native States has been as follows: In July, 8987 deaths; August, 14,191; September, 28,618. There is very little plague in Northern India, only 13 deaths from it being recorded in the Punjab during September, but a severe epidemic has broken out in the Bombay Presidency, where 20,470 of the total number of deaths in September occurred. Madras and Mysore are also affected, though in a slighter degree.

The Prevalence of Anterior Poliomyelitis.

Mr. EDMUND HARVEY asked the President of the Local Government Board whether his attention had been called to the prevalence during the past year in certain districts in Yorkshire of the disease known as anterior poliomyelitis; and whether, in view of the character of the disease and its serious after-effects, he would cause investigations to be made into the nature of the disease, with a view of discovering the best means of cure and of avoiding its spread.—Mr. BURNS wrote in reply: My attention has been drawn to the prevalence of acute poliomyelitis not only in certain districts of Yorkshire, but also in several other counties, and three of my inspectors have for a considerable time past been engaged in investigations relating to it, the results of which along with information as to the pathology of the disease will be published in due course.

WEDNESDAY, NOV. 1ST.

Medical Men and the Royal Naval Reserve.

Mr. MIDDLEMORE asked the Secretary to the Admiralty whether any steps had been taken to induce medical men to take commissions in the Royal Naval Reserve, with a view to securing their professional services in war time, or whether such a step was in contemplation?—Mr. MACNAMARA said in reply: We have done a great deal in the direction suggested by the honourable Member. Revised regulations for medical officers, Royal Naval Volunteer Reserve, embodying improved conditions of service have recently been introduced and have been brought prominently to the notice of medical men throughout the country. The result so far is considered satisfactory.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, London, W. LONGMANS, GREEN, AND CO., New York.

International Medical Monographs. General Editors: Dr. Leonard Hill, F.R.S., and Dr. William Bulloch. Syphilis from the Modern Standpoint. By James McIntosh, M.D. Aberd., Grocer's Research Scholar, and Paul Fildes, M.B., B.C. Cantab., Assistant Bacteriologist to the London Hospital. Price 10*s.* 6*d.* net.

Price Fr.10.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ADAMS, MARTHA, M.B., B.S. Glasg., has been appointed Lady Medical Inspector to the Essex Education Committee for six months.

ALDERSON, G. G., M.B., B.C., has been appointed Obstetric Assistant to University College Hospital.

BARBER, P. E., L.R.C.P. Lond., M.R.C.S., has been appointed Professor of Midwifery in the University of Sheffield.

BARRIS, J. D., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Assistant Physician to the City of London Lying-in Hospital.

BENTON, GRAHAM M., M.B., Ch.B. Vict., has been appointed Sixth Anæsthetist to the Manchester Royal Infirmary.

BRENTNALL, C. G., M.B., Ch.B. Vict., has been appointed House Physician at the Manchester Royal Infirmary.

BUCK, HOWARD, M.B., Ch.B. Vict., F.R.C.S. Eng., has been appointed Resident Surgical Officer at the Manchester Royal Infirmary.

CHILD, W. N., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the British Lying-in Hospital.

CHUBB, G. C., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at University College Hospital.

CONDY, E. M., M.B., B.Ch. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Clonavaddy District of the county of Tyrone.

COOPER, F. W., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Trillick District of the county of Tyrone.

COURTS, A. C. S., M.B., B.S. Lond., has been appointed House Physician at University College Hospital.

CRESSWELL, FRANK PEARSON SKEFFINGTON, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed one of the Medical Referees under the Workmen's Compensation Act for County Court Circuits Nos. 24, 30, and 31.

DARLING, H., M.B., B.S. Lond., has been appointed House Physician at University College Hospital.

DIXON, JOSEPH FRANCIS, M.D. Dub., has been appointed Medical Superintendent of the Leicester Borough Asylum.

DOWNING, C., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Cardiff District of the county of Glamorgan.

FOWLER, W. C., M.B., B.S. Lond., has been appointed House Surgeon at University College Hospital.

HEDLEY, JOHN PRESCOTT, M.B., M.C. Cantab., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed Physician to Out-patients at the British Lying-in Hospital.

HEY, WILSON H., M.B., Ch.B. Vict., F.R.C.S. Eng., has been appointed Visiting Surgeon to the Manchester Children's Hospital, Medical Superintendent to the Christie Cancer Hospital, Manchester, and Assistant Surgical Officer to the Out-patient Department at the Manchester Royal Infirmary.

HIBBERT, CECIL, F.R.C.S. Edin., has been re-appointed Medical Officer to the Central Branch of the Manchester Royal Infirmary.

HUTCHINSON, JAMES RANDAL, M.D. Vict., D.P.H., has been appointed Medical Inspector under the Local Government Board.

MORLEY, JOHN, F.R.C.S. Eng., has been appointed Surgical Registrar to the Manchester Royal Infirmary.

PHILLIPS, MILES H., M.B. Lond., F.R.C.S. Eng., has been appointed Lecturer in Gynæcology in the University of Sheffield.

PYE-SMITH, Professor R. J., Ch.M. Sheffield, F.R.C.S. Eng., has been appointed to represent the University of Sheffield on the General Medical Council.

SCOTT, ALEX. R. P., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Physician at the Prince of Wales's General Hospital.

SHATTOCK, C. E., M.B., B.S. Lond., has been appointed House Physician at University College Hospital.

STEPHEN, DAVID, M.B., B.S. Aberd., has been appointed Assistant Medical Officer at the Lincoln Mental Hospital.

VAUGHAN, R. G., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Caldicot District of the county of Monmouth.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYR DISTRICT ASYLUM.—Junior Assistant Medical Officer. Salary £140 per annum, with board, lodging, and laundry.

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £80 per annum, all found.

BATH ROYAL UNITED HOSPITAL.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Resident Medical Officer for six months. Salary at rate of £60 per annum, with board, residence, &c.

BIRMINGHAM CITY ASYLUM, Winson Green.—Junior Assistant Medical Officer. Salary £150 per annum, with board, laundry, &c.

BIRMINGHAM, CITY EDUCATION COMMITTEE.—Medical Officer for Inspection of School Children. Salary £260 per annum.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CAMBRIDGE COUNTY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £160 per annum, with board, lodging, and attendance.

WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.

WEST AFRICAN MEDICAL STAFF.—Appointments. Salary £400 per annum.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, &c., 73, Welbeck-street, W.—Clinical Pathologist for six months. Salary £50 per annum.

WHITTINGHAM, NEAR PRESTON, COUNTY ASYLUM.—Pathologist and Assistant Medical Officer. Salary £200 per annum, with board, apartments, and washing.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician. Salary £80 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

WREXHAM INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Tottenham, in the county of Middlesex; and at Dumfries, in the county of Dumfries.

Births, Marriages, and Deaths.

BIRTHS.

BATES.—On Oct. 29th, at Vicars-hill, Lewisham, S.E., the wife of George Llewellyn Bates, L.R.C.P., M.R.C.S., L.D.S., Harley-street, W., of a son.

WEBB.—On Oct. 28th, 1911, at 119, Elgin-crescent, Notting Hill, W., the wife of W. S. Webb, M.D., L.R.C.P., &c. (late West African Medical Staff), of a daughter.

DEATHS.

PULLIN.—On Oct. 26th, at Abernethy House, Sidmouth, Thos. H. S. Pullin, M.D., F.R.C.S. Edin., aged 87 years.

STANLEY SMITH.—On Oct. 25th, at 68, Wimpole-street, Cavendish-square, peacefully after a short illness, E. Stanley Smith, M.D., M.R.C.P., aged 59 years. Funeral at Kensal Green at 3.30 on Saturday, Oct. 28th. Friends please accept this, the only intimation.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A MEDICAL OFFICER'S SALARY.

BOARDS of guardians, as is only too well known to the medical profession, do not always err on the side of generosity and sympathy towards their medical officers. An account in the *Bradford Observer* of a recent meeting of the Bradford board of guardians reveals a condition of over-work and under-pay in the terms of employment of the medical officer of No. 1 district under that board which calls for public attention, particularly at a time when the amount and method of remuneration for medical service has become a public question. We learn that the deputy chairman of the Bradford board of guardians proposed that, subject to the consent of the Local Government Board, the salary of this medical officer should be increased from £50 to £100 per annum, exclusive of medicines and dispensing, which should in future be provided by the guardians. In answer to a critic the deputy-chairman justified his proposal by the statement that "the doctor had spent all the money allowed him in medicines; he had had nothing for himself. During the past year he had made no fewer than 3500 visits, which ran out at 3½*d.* per visit, so that really the doctor did not get paid for the medicine he gave, and the guardians thought it was time for every man to receive his hire." It is satisfactory to note that the motion was carried without further ado.

CHOLERA AND PLAGUE IN RUSSIA.

Mr. A. W. Woodhouse, British Consul at St. Petersburg, in his report for the past year just received at the Foreign Office, writes: "During 1910 conditions of public health in Russia were severely tried by a recurrence of plague and intensification of the cholera epidemic which had prevailed for three years previously on a much smaller scale. This increase of cholera is shown in the following comparison of figures for the past four years:—

Year.	Provinces and territories affected.	Cases.	Deaths.
1907	50	12,717	6,442
1908	69	30,709	15,543
1909	49	22,632	10,605
1910	72	216,091	101,002

The epidemic raged throughout the year without interruption from the time of its reappearance in the spring in Southern Russia. The chief nurseries of the disease appeared to be at two or three points in the province of Ekaterinoslav, especially in the district of Bakhmut, which is the seat of mining industries and several great ironworks, employing many thousands of workmen. From here it spread over the country through Rostov-on-the-Don and Baku, the latter district having been the centre whence the Caucasus and trans-Caucasus received the contagion. The attention of the Russian authorities in combating the epidemic was chiefly directed to sanitary precautions and medical assistance along the courses of the principal water-ways. Every boat carrying passengers was placed under the observation of a medical officer on board, and 71 medical stations were established along the Don, Volga, Dvina, Neva, the Ladoga Canal system, and the rivers of Siberia.

"The first outbreak of bubonic plague in 1910 occurred at Odessa in the middle of May, and from that time until the end of November there were 140 cases, 42 of which ended fatally. The general medical opinion was that the contagion had been brought to the town by the sea. One more solitary case was disclosed there in December, and two or three deaths from plague occurred also at Batoum and Baku. A region more seriously affected by it was the Kirghiz Steppe in the province of Astrakhan, where 180 deaths took place out of 226 cases. A special medical commission of inquiry was sent into this district in the autumn. The character of the disease seems to change from bubonic in summer to pulmonary plague in the cold season. The greatest danger was from the Russian railway zone of the Chinese Eastern line through Manchuria, where 1043 Chinese and 32 Europeans contracted the disease, and 1020 Chinese and 29 Europeans died of it, between Oct. 26th, 1910, and Jan. 27th, 1911."

THE GALE AND SANITATION.

A CORRESPONDENT writes: "From the public health standpoint the value of the gale on the south coast last week is apt to be overlooked. Watching the great waves dashing on the beach the mind is carried away, firstly, by the magnificent spectacle afforded by the rough sea; and secondly, by the sight of the damage done to the foreshore. Considering the fierceness of the gale the damage done was comparatively slight, while the benefit derived must be an important consideration to health resorts. The gale drove the sea at high tide over the entire beach, not stopping at what is known as high-water mark and in many cases trespassed even much further. The result was that the accumulation of stones was thoroughly cleansed by sea water. It must be borne in mind, too, that such a cleansing process had not taken place since the previous gale in December. However careful local authorities are over their beach at the seaside they cannot cleanse it in the way it is periodically purified by a rough sea. More than ever was this cleansing process needed on this occasion after the long period of drought and great heat."

A DANGER TO HEALTH IN PUBLIC ELEMENTARY SCHOOLS.

To the Editor of THE LANCET.

SIR,—When our legislators framed their education laws they seem to have forgotten to arrange for fine weather to be provided for the carrying out of their grand educational scheme. The result of their forgetfulness has been the illness and death of many children who have reached school after exposure to heavy rain drenched with wet, and in this state they have gone through three hours' schooling. It has been stated by a judge that "attendance is not legal if a child is not in a fit state to attend." It is evident that if a child is dangerously wet he is not in a fit state, because he may contract a severe illness. Therefore, in the absence of the school doctor it should be the duty of the teacher to dry the clothes, or, if that is impossible, the child should be sent home. Very few, if any, of the medical inspectors have called attention to this matter.

The coöperation of the parents should be obtained in order to protect the children from this risk, but parents have been reduced to indifference to the welfare of their children by the action of some of the school attendance officers. Some of these officials regard themselves as competent to decide whether the explanations of the parents for the absence of their children are valid or not. Their duty is only to ask the parents the cause of absence and then report to the authority. An effort should be made to encourage parents to use their discretion as to when it is right to keep a child at home. Health is the best of all gifts, and should not be damaged or hazarded for a smattering of learning. Wet clothes often prove the starting-point of incurable disease.

I am, Sir, yours faithfully,

Torquay, Oct. 30th, 1911. H. H. TIDSWELL.

AN "AMMOCHLORIQUE" INHALER.

FOR the production of ammonium chloride fumes, simulating smoke, this apparatus answers well. It is small and compact and simple in action. In form it is like an ordinary hooked tobacco-pipe, the glass bowl containing the "laboratory" in which ammonia and hydrochloric acid are brought together to form ammonium chloride. The reagents are contained in glass bulbs with easily fractured tube ends. A wetted sponge is placed at the bottom of the bowl and the contents of a fractured ammonia tube are allowed to drop upon it. Next a sealed pipette of hydrochloric acid is placed in an open glass tube fitted into the rubber stopper of the bowl. On breaking off the ends of the pipette the acid falls into a small bulb at the lower end of the tube provided with an exit hole. Air drawn through the pipe by means of suction at the stem mouthpiece is first charged with hydrochloric acid. It then encounters the sponge saturated with ammonia when ammonium chloride is formed which reaches the respiratory organs in the state of smoke. The apparatus was submitted to us by Messrs. C. J. Hewlett and Son, Limited, of 35-42, Charlotte-street, London, E.C.

THE WOES OF A PUBLIC VACCINATOR.

To the Editor of THE LANCET.

SIR,—The enclosed may be worthy of a corner in your paper under the above title:—

P.V.: "Well, Mrs. ——, do you wish me to vaccinate your baby this morning?"

Mrs. ——.: "No thank you, sir, my husband says he would rather pay and have it done properly."

I am, Sir, yours faithfully,

Oct. 28th, 1911. R. B. F.

"AURORA" HEALTH CARAVAN.

FOR the past three months the "Aurora" Health Caravan—belonging to the Women's Imperial Health Association of Great Britain, of which H.R.H. Princess Louise Duchess of Argyll is Patron—has been touring the West of England under the charge of Major C. A. Thimm, who may be remembered as being formerly connected with the Sleeping Sickness Bureau, Burlington House, and whose "Bibliography of Trypanosomiasis" is a standard work of reference on that subject. During the tour Major Thimm held open-air meetings in all the villages through which he passed, and gave simple and instructive "Health Talks," and when visiting cities and the large towns public halls were engaged and well-known medical men and others sent from London to lecture on behalf of the association, among whom have been Dr. David Walsh ("Infant Mortality," "Teeth in Connexion with the Health of the Nation—Medical Side"); Dr. Murray Leslie, the chairman of the association ("Prevention of Consumption"); Mr. George Thomson, L.D.S. ("Teeth in Connexion with the Health of the Nation—Dental Side"); Dr.

Lilian Simpson ("Home Nursing"); Dr. J. G. Garson ("Hygiene of Consumption"); and Mr. C. G. Moor, M.A., F.I.C. ("Foods for Grown-Ups, Children, and Babies"). Major Thimm received from the medical officers of health of the districts he travelled through the greatest assistance and encouragement.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for November, 1911:—

September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 31st–Nov. 4th (London, Royal Horticultural Hall).—Twenty-second Universal Cookery and Food Exhibition.
Nov. 1st–14th (London).—"The Englishwoman" Exhibition of Arts and Handicrafts.
,, 3rd–11th (London, Olympia).—Tenth International Motor Exhibition.
,, 9th–11th (Cape Town).—Congress of the South African Branch of the Royal Sanitary Institute.
,, 10th–25th (Manchester).—Smoke Abatement Exhibition.
,, 14th and 15th (Vienna).—Jubilee of Union of Austrian Dental Surgeons.
,, 21st–23rd (Montreal).—Canadian Public Health Association (First Annual Meeting).
November (Rome).—Fourth International Congress of Physical Education.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

LABORATORY MEETING, Lister Institute, Chelsea Gardens, S.W. (nearest station, Sloane-square).

Dr. Bayon: (1) Demonstration of Organisms from Cases of Leprosy; (2) Attempts to Differentiate various Acid-fast Organisms by Complement-fixation and Animal Tests.
Prof. E. A. Minchin: Demonstration of Intracellular Phase of *T. Lewisi* in the Stomach of the Flea.
Dr. Funk and Dr. Cooper: Demonstration on Pigeon Beri-beri.
Dr. Funk: The Cause and Cure of Beri-beri.
Dr. H. C. Ross and Dr. Cropper: Demonstration of Division-figures in Lymphocytes.
Dr. E. H. Ross: The Developmental Cycle of the Lymphocytozoon of the Guinea-pig (Kurloff's Body).
Dr. Henderson-Smith: The Immunisation of Rabbits with Varying Doses of Typhoid Vaccine.
Dr. Priestley: An Attempt to Differentiate the Diphtheroid Group of Organisms.
And other Papers and Demonstrations.

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.

Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 8.30 P.M.

Cases:
Dr. W. Essex Wynter and Mr. J. Murray: Toxic Cirrhosis, with Splenoportal Thrombosis and Ascites (Banti's Disease) treated by Femoral Drainage.
Dr. H. P. Hawkins: (?) Splenic Anæmia with Question of Excision of the Spleen.
Dr. N. S. Finzi: Malignant Growth of the Cheek which has Disappeared under Radium Treatment.
Dr. Reginald Miller: Hæmochromatosis with Diabetes.
Mr. W. Sampson Handley: Ivory Exostosis of the Frontal Sinus.
Dr. Norman Dalton: (1) Malignant Anæmia, Hæmolytic Type; (2) Malignant Anæmia, Aplastic Type.

Paper:
Prof. Rogers: The Treatment of Cholera by the Intravenous Infusion of Hypertonic Saline Solution.

(Members of the Epidemiological Section are specially invited to attend this meeting.)

HUNTERIAN SOCIETY, Metropolitan Hospital, Kingsland-road, N.E.

WEDNESDAY.—4 P.M., Clinical Afternoon.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., Lieut.-Col. H. E. R. James, C.B., and Major C. E. Pollock, R.A.M.C.: Medical Arrangements in the Field, with Special Reference to the Functions of the Clearing Hospital.

NEW LONDON DERMATOLOGICAL SOCIETY, Western Skin Hospital, 179, Great Portland-street, W.

THURSDAY.—4.30 P.M., Dr. D. Walsh: The Influence of Cardiac Valvular Disease upon Cutaneous Disorders. Clinical Cases.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Specimen will be shown by Mr. F. Moore. 8.30 P.M., Prof. Straub (Amsterdam): The Pathology of Dust-like Opacities in the Vitreous Body and of Descemet-dots.—Mr. A. Ormond: Ocular Conditions found in Mongolian Idiots.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

TUESDAY AND FRIDAY.—5 P.M., Major H. C. French: Syphilis.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. P. Dunn: Diseases of the Conjunctiva.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical, with cases.
WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine. (Lecture II.).
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Bernstein: Blood Examinations—Serology.
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Pardoe: Clinical (Urinary Surgery).
SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Mr. W. Turner: Empyema.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. J. Taylor: Ocular and Visual Signs and Symptoms in Nervous Disease.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).
TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. W. H. Duncan: The Etiology, Pathology, and Bio-chemistry of Malignant Disease.
WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie). 4.30 P.M., Lecture: Mr. R. P. Brooks: The Conjunctiva in Health and Disease.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Maguire.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Batten: Muscular Atrophy.
FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. P. Sargent: Trigeminal Neuralgia.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lecture:—Dr. D. McKenzie: Ear.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. K. Sibley: Treatment of Skin Diseases by Hyperæmia.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Syphilis (continued): Papular (I., Miliary; II., Lenticular; III., Squamous; IV.. Moist), Pustular (I., Small; II., Large), Nodular and Gummatous.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

MONDAY.—5 P.M., General Meeting.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. W. J. S. Bythell: X Ray Diagnosis of Stone in the Kidney. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.) Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.,, Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (11th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A

METEOROLOGICAL READINGS.

The Hunterian Lectures
ON
RECENT DEVELOPMENTS IN HE RECOGNITION, TREATMENT, AND PROPHYLAXIS OF SYPHILIS.

Delivered before the Royal College of Surgeons of England on Nov. 7th and 10th, 1911,

BY H. C. FRENCH, M.R.C.S. ENG., L.R.C.P. LOND.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

LECTURE I.

Delivered on Nov. 7th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—In being honoured by the request of your Council to deliver two Hunterian lectures the mind unconsciously turns to the time-honoured name of John Hunter.

VALUE OF HUNTER'S OBSERVATIONS ON INDURATION.

His demonstration of induration in the syphilitic (Hunterian) chancre in the primary stage, as a clinical sign of early syphilitic infection is, after the lapse of over a hundred years, a more infallible indication when it exists than a positive Wassermann-Neisser-Brück serum diagnosis reaction. Further, such induration is commonly present when the spirochæta pallida of Schaudinn, discovered in March, 1905, cannot be demonstrated. From time to time persons have attempted to detract from the great value of Hunter's work on syphilis because he erroneously taught that gonorrhœa and syphilis were one and the same disease. Owing to Hunter's initial error we have sometimes been asked to set aside all authoritative teaching. We must not forget, however, that his was necessarily an age of dogmatism, and that other portions of his clinical teaching, like Sir Astley Cooper's classification of dislocations of the hip-joint, have stood the test of time and the judgment of posterity—the best criterion of all good work. As Cicero says, "Men in their lifetime plant trees for another generation to benefit by."

It is not by any means rare to see men or women simultaneously suffering from the two diseases, gonorrhœa and syphilis, and, occasionally, from scabies and non-infecting chancre in addition. In some instances, before the gonorrhœa resolves, a syphilitic chancre, or even rash, may be developing. I have notes of many such cases. I note in particular a man with gonorrhœa, who developed in hospital a syphilitic chancre in the calf of the left leg with discretely enlarged glands, followed within three months by a roseolar rash.

Another difficult case occurred in association with gonorrhœa where there was a deep-seated indurated mass on the under surface of the penis about an inch from the meatus urinarius. I asked a Fellow of this College to kindly open the abscess. He sent the man off the operating table as he considered that there could be no possible doubt that it was a Hunterian indurated urethral chancre. As urethral syphilitic chancres ordinarily occur at the meatus, and I had seen other cases of this nature, I opened the supposed chancre in his presence, and on deep incision the pus flowed freely from a peri-urethral abscess, and syphilis did not later supervene. Phimosis in association with purulent balanitis may or may not mask an underlying syphilitic ulcer, the real nature of which is only disclosed on operation, or later. The gonococcus may occasionally be demonstrated in a purulent balanitis and no urethral discharge be present.

With such a multiplicity of possible contingencies and no ultra-microscope, Hunter's mistake is excusable. The correctness, however, of the clinical fact of induration in a syphilitic chancre in association with discrete enlargement of adjacent lymphatic glands is a bequest the value of which has been insufficiently realised. At the present time there is a tendency, more especially in dealing with early syphilis, to set on one side valuable clinical facts in favour of bacteriological methods, and to pronounce an infallible verdict on the sole evidence of a Wassermann reaction. This test, in my experience and in that of other persons, may sometimes be negative when constitutional manifestations of syphilis are present, and not infrequently positive in non-syphilitic conditions.

I propose with your kind indulgence to deal with the diagnosis of early syphilis from three points of view: (1) Demonstration of spirochæta pallida of Schaudinn; (2) Wassermann-Neisser-Brück serum diagnosis reaction; and (3) clinical evidence.

I. DEMONSTRATION OF SPIROCHÆTA PALLIDA.

Major L. W. Harrison, R.A.M.C., at Rochester-row Military Hospital, states that he only succeeded in demonstrating the spirochæta pallida in 152 out of 202 cases of syphilitic sores. He suggests that in the remaining 25 per cent. of cases local antiseptics or other causes may have prevented the demonstration. Another observer found the spirochæta in 35 out of 52 cases of syphilis.[1] It is instructive to realise that local antiseptics have this valuable bactericidal property, which is equally applicable to all stages. Stress was laid by me on this very point 13 years ago, in writing that[2] "The application of the rules of antiseptic, aseptic, and general surgery to the wounds of syphilis is valuable in proportion to the extent and manner in which they are used. It is noticed what extremely successful results follow the removal of the local products of pus formation." Mr. Ernest Lane, referring to the exudate from initial lesions, states: "I have encountered several cases in which the treponema was not discovered after repeated examinations, and in which the case ultimately proved to be one of syphilis." This is a not infrequent experience, and I have seen numerous failures in the hands of skilled and highly trained observers to demonstrate the spirochæta pallida in chancres that were obviously syphilitic. The organism probably lies embedded in fibrous indurations, and in some cases may be demonstrated in sections.

Dr. Reinke, at Wiesbaden in 1910, demonstrated granules in the lung of a child in an autopsy performed after treatment by salvarsan. The granules were derived from spirochætæ.[3] Dr. Balfour considers[4] "that granule shedding in treponema pallidum occurs before any treatment of the case is begun. It is, therefore, in all probability a feature in the life-history of the spirochæta. ..... The same is true of other spirochætes associated with that of syphilis, and is specially well seen in the case of spirochæta refringens. ..... The granules being of the nature of resistant spores, and so far as those derived from T. pallidum are concerned, doubtless play an important part in relapses and in the later manifestations of syphilitic infections."

The fact that in syphilitic chancres several varieties of spirochætæ exist and naturally shed granules suggests for our consideration whether there is any developmental relationship between these numerous varieties of spirochætæ always found in association in the primary syphilitic chancre. It is only in the blood and under scabs or in lesions of true constitutional syphilis that we find the treponema pallidum apart from other spirochætæ. We have an analogy for such possible development in the case of other organisms, as, for instance, paratyphoid organisms and those of Eberth's bacillus of enteric fever.

Noguchi[5] recently claims "to have made pure cultures of the spirochæta pallida which were pathogenic for the rabbit, and produced diseases identical with those set up by syphilitic material. ..... Two strains of the spirochæta pallida in pure culture were obtained, and when inoculated into the testicle of the rabbit gave rise to typical lesions containing numerous spirochætes." Other observers point out in this connexion[6] "that experimental investigations in syphilis have become more general since the demonstration by Tomaczewski of a testicular infection in the rabbit. This animal is more suitable than monkeys on the score of expense, the lesions are well localised for observation and are very rich in spirochætæ. Positive inoculations are readily obtained on the skin of the scrotum or deeply into the testis. Some disadvantage is, however, to be found in the fact that in the rabbit the disease is practically local and liable to spontaneous cure. No generalised symptoms are observed, although the virus is demonstrable in the internal organs by means of inoculations of these organs into other animals." What are we to infer from this? Has the rabbit special properties in its blood which prevent the evolution of external generalised manifestations of syphilis?

A principal feature of this disease in man is a repeated and long-continued series of skin and nervous symptoms. Syphilis in man may also undergo spontaneous cure. Hata worked extensively on the rabbit when determining the value of "606" In America the question has arisen whether experiments on herbivorous animals can be fairly contrasted with, or are as conclusive as, those on monkeys or on man?[7]

II. WASSERMANN TEST.

Coming to my second heading—namely, Wassermann serum diagnosis tests—it is proposed to deal with this question from the clinical side, as the purely pathological aspects have already been so ably portrayed last year by Professor Emery in his Hunterian lectures on Immunity Reaction in Diagnosis, especially of Tuberculosis and Syphilis. As laboratory methods and clinical facts relating to the Wassermann test do not always coincide, the results of some Wassermann tests, independently performed on cases under my care by Captain T. H. Gibbon, at the Pathological Laboratory, Malta, may prove of interest.[8] The controls, with few exceptions, were negative in the case of soldiers giving no history of syphilis. In the primary stage the results, in conformity with the experience of others, were not infrequently disappointing. In the secondary stage, however, in cases on their first course of mercurial treatment, or earlier, the results were stated to be positive in 40 out of 43 cases. These were usually men with unquestionable constitutional syphilis, the larger number having been recently placed on the syphilis register.

The reaction was positive in 14 out of 18 cases who were on their second, third, or fourth course of mercurial treatment by injections of intramuscular insoluble grey oil. In one negative case with recent syphilis the man was a heavy drinker. The test was further applied to 36 other cases of men who had completed two years' regular mercurial treatment by the above method; the reaction was positive in 25 out of 36 cases. In one of the negative cases the man was suffering from mercurial stomatitis. In another negative case gummatous ulceration was actually present.

These results were obtained with Fleming's modification of Wassermann and, as regards secondary syphilis, compare favourably with those obtained by Wassermann's original method. As regards early syphilis the results are difficult to interpret, and I therefore quote the cases in detail.

Results of Wassermann Reaction in Early Cases.

CASE 1.—Lance-Corporal A was admitted on 6/11/09 with a non infecting chancre, no induration, and suppurating buboes, both inguinal; operation. No mercury given. On 30/11/09 the Wassermann test was "positive." He was discharged hospital on 16/12/09. Syphilis did not later supervene.

CASE 2.—Private B was admitted on 22/11/09 with a non-infecting chancre situated on corona glandis. Local treatment; no mercury. On 28/11/09 chancre healed; no evidence of induration. Suppurating left inguinal glands, for which an operation was performed. Wassermann test "positive" on 13/12/09, and "negative" on 26/12/09. Syphilis did not later supervene.

CASE 3.—Private C, admitted on 11/1/10 to 28/1/10. Small non-indurated ulcer on tip of prepuce, and a suppurating bubo right inguinal glands, which burst on 12/1/10. Local treatment. No mercury. 27/1/10, Wassermann doubtful. Syphilis did not supervene.

CASE 4.—Private D was in hospital from 8/11/09 to 23/11/09 with a non-indurated ulcer on the frenum; inguinal glands normal. The Wassermann test was "positive" on 9/12/09 The case, on this sole evidence, was diagnosed syphilis and placed on the syphilis register. The principal medical officer was referred to, and caused the soldier to be medically re-examined by a second medical officer. There was no clinical evidence of syphilis, nor did that disease later supervene. The principal medical officer directed the case to be erased from the syphilis register.

CASE 5.—Private E was in hospital 24/8/09–4/9/09. Local treatment; no mercury. The Wassermann test was "positive" on several occasions, the last occasion being 27/11/09. He was placed on the syphilis register on this sole evidence on 31/12/09. There was no clinical evidence of syphilis then or since. The case was similarly dealt with as with case No. 4.

CASE 6.—Gunner F, admitted from 3/11/09–25/11/09. No induration of chancre. Inguinal glands: one gland only slightly enlarged as the result of simple inflammatory action, which subsided under local treatment; no mercury. Wassermann "negative" 25/11/09, and "positive" 28/12/09. Syphilis did not supervene.

CASE 7.—Private G admitted from 13/12/09–23/12/09. Slight abrasion, no induration inguinal glands normal. Local treatment; no mercury. Wassermann "positive" 20/12/09. Syphilis did not supervene.

CASE 8.—Private H, admitted 15/12/09–7/1/10. Abrasion glans penis, inguinal glands normal. Local treatment; no mercury. He had also a suspicious unhealthy ulcer on the knuckle, and the lymphatic glands above the elbow on the same side were enlarged but tender. Local treatment; no mercury. Wassermann test "positive." Syphilis did not supervene.

CASE 9.—Private I was admitted on 28/11/09 to 31/12/09. Multiple sores, due to secondary inoculation from one near frenum. No induration. Inguinal glands normal. Wassermann test "positive" 31/12/09. Syphilis did not later supervene.

CASE 10.—Rifleman J was admitted on 15/9/09–10/11/09. Large ulcer 1 in. long. No induration. Inguinal glands normal. Local treatment; no mercury. Wassermann test "positive" on 28/12/09 and on 31/12/09. Syphilis did not supervene.

CASE 11.—Private K, admitted on 13/2/11 with an indurated fissured chancre on dorsal aspect of the roll of prepuce reverted. Large hyperplastic mass superficially suppurating in left inguinal region for which an extensive operation was performed on 22/2/11. On 8/3/11 the Wassermann test was negative. Treatment by mercurial inunctions was resorted to in despite of the test. On 30/3/11 superficial glossitis present, but induration of chancre much reduced. 19/4/11 discharged hospital, to continue mercurial injection treatment as out-patient. In June, 1911, he was readmitted to hospital with well-marked typical patchy syphilitic alopecia on occiput. Anæmic, no rash to date 1/7/11, when he was discharged hospital.

Value of the Test.

The question of the value of the Wassermann reaction in the diagnosis of early syphilis was raised from the clinical side a year ago. I wrote[9]:—

> The test, in the primary period, is unfortunately very uncertain, and not infrequently in my experience when a negative result has been recorded syphilis has later supervened. .....
>
> In some ten to twelve instances, recently, at Malta, in which the result was reported to me as positive in cases of chancres, and where mercurial or other treatment was not employed, syphilis did not supervene. The chancre and the glands in these instances were not indurated or discretely enlarged. It may be said that the test was defective. Possibly, but the pathologist obtained 98 per cent. of positive results in secondary cases—that is, after rash had occurred.
>
> In the case of an officer recently who suffered from arterio-sclerosis associated with a clear history of antecedent syphilis, the test was strongly positive according to one reliable laboratory opinion in London, and yet three weeks later, without treatment, a negative result was reported from another laboratory. In other instances the test may be negative, and later positive, or *vice versâ*, without any material change in the immediate surroundings of the patient.
>
> The test, therefore, in order to be conclusive, requires to be standardised. In order better to ensure scientific accuracy it might be preferable that the clinical signs should be unknown to the pathologist who performs the test. Such independent results are more convincing.

Following this, another observer from the clinical side states[10]:—

> We are not disposed to place too implicit reliance upon the presence or absence of Wassermann's reaction in coming to a diagnosis, for our experience is that perfectly definite cases of syphilis with actual lesions at the time of examination may repeatedly give negative reactions.

Another observer, who has unrivalled opportunities at the London Lock Hospital, both from the clinical and pathological standpoint, stated at the meeting of the British Medical Association this year[11]:—

> Let me emphasise once again that a Wassermann reaction in the primary stage of syphilis is valueless, since the moment this reaction becomes positive the secondary or stage of general infection has been reached.

Mr. H. W. Bayly states[12]:—

> I have personally examined well over 2000 sera. It seems to me, however, that the most essential of all factors in a comparative test such as this is that all factors except the one to be tested should be constant. With Hecht's, Bauer's, Stern's, or Fleming's technique variants are substituted for constants.

Major L. W. Harrison states:—

> In his hands the modification by Stern has given a positive reaction in about 2 per cent. of normal cases. ..... And gives a positive reaction earlier than the original.

On the foregoing evidence are we prepared to accept unquestioned the dogmatic bacteriological assertion of Dr. Paul Fildes?[13]—

> 1. That from a positive finding there is within certain understood limits no appeal; the individual yielding such a result is, again within certain limits, to be regarded as actively syphilitic and must be treated as such.

The same writer further states that—

> It is well known that many cases give negative results when obviously syphilitic.

Another bacteriologist, in reviewing a recent work on the subject, states[14]:—

> 2. A number of the histories failed to convince us of the syphilitic nature of the symptoms. For instance, a case of pernicious anæmia is attributed to syphilis on the grounds of a specific history and a positive Wassermann reaction. In this, and in some other instances, the author seems to have fallen into the error of labelling every lesion syphilitic which coincides with a positive Wassermann reaction with or without a specific history. We are convinced that nothing is more likely to bring the test into discredit than allowing the presence of a positive Wassermann reaction to blind us to possible causes other than syphilis for the symptoms which a patient may display.

Boas[15] emphasises the importance of "carrying out all Wassermann's reactions in a quantitative manner—a method which is impossible in the case of all the ordinary suggested modifications. He obtained much better results with the original test in a quantitative manner, and stated that the Wassermann reaction has not, and will not, obviate the necessity for clinical observation in syphilis."

In a recent leader on the subject in the *British Medical Journal* a writer states [16]: "Even among laboratory workers confusion has arisen by reason of the number of modifications and simplifications of Wassermann's original process. Before we can truly estimate the accuracy and reliability of the test it is essential that the relative merits of the original method and of all modifications should be decided, if necessary, by the establishment of a committee of enquiry."

In addition to a positive Wassermann reaction in the ten cases previously cited of unquestionable non-infecting (soft) chancre at Malta, positive results have also been obtained by other observers in various non-syphilitic conditions, such as gonorrhœa, scarlet fever, yaws (fairly constant), leprosy (very high percentage, especially in the tubercular variety), malaria (35 per cent. before the administration of quinine), puerperal eclampsia, lupus erythematosus, trypanosomiasis, pneumonia, enteric fever, tumours, herpes, aortic disease, relapsing fever (54 per cent.), alopecia areata, in some persons under narcosis and in dead bodies. As regards the latter, of 101 specimens of serum from cadavera 59 (that is, 60 per cent.) gave a positive reaction.[17] Sabouraud of Paris is now of opinion that extensive alopecia areata is more commonly due to syphilis, either acquired or hereditary, than to any other single cause.[18] Du Bois investigated 14 cases of alopecia areata typical in every respect, and in 11 found a positive Wassermann reaction where there were no symptoms of syphilis, hereditary or acquired.[19] Dr. J. H. Sequeira of the London Hospital, in showing a case of alopecia areata in a syphilitic subject at the Dermatological Society of London in July, stated "that he had had a number of cases of alopecia areata examined by the Wassermann test, but that this was the only instance in which a positive reaction had been obtained."[20]

In latent syphilis where manifestations are absent Boas only obtained 37 per cent. of positive results, as contrasted with 97 in secondary and 95 per cent. in tertiary manifestations.[21] It is interesting to consider what is the meaning of this test? Can it be dependent on an excess of albuminous or other products of disintegration arising from increased metabolism?

Before coming to my final heading and dealing with some clinical aspects in the diagnosis of early syphilis, I propose placing a few specimens on the screen. This is in accordance with the usual custom in order to demonstrate material in the Museum of the College. Owing to a large number of the wax models and paintings being too large for the epidiascope your indulgence is craved if the choice of material is somewhat limited.

III. CLINICAL EVIDENCE.

I put the clinical aspect last, but in my opinion it is by no means the least valuable. It does not perhaps glitter like the gold of the spirochætæ, nor sound like the brazen cymbal of a positive Wassermann reaction, but as regards induration in the chancre it has the intrinsic merit of home manufacture. Sir Jonathan Hutchinson states: "If the patient has never had syphilis before, whatever are the characters of any primary sore which he may exhibit, the chances are two to one that the sequel will prove that it contained the germs of true syphilis." Owing to advantage having been taken of this statement by certain persons to unduly extol the claims of several new remedies in the therapeutics of syphilis, I have studied this point closely for many years amongst some thousands of in-patients. In the British army, in England and abroad, where numerous cases of venereal sore come under early notice, soldiers are first treated in hospital. Commencing, however, from September, 1903, men on discharge from hospital remain under continued observation. Exact diagnosis on clinical grounds is thus more feasible than in civil life, where cases are wholly treated as out-patients, where their actions are uncontrolled, and where they commonly communicate disease to others. Relative frequency is dependent on numerous factors, such as epidemicity. Soldiers, more especially in England, may resort to civil practitioners and chemists in order to avoid loss of pay by reason of admission to hospital. No doubt in civil practice many cases are only seen by specialists when there is a strong probability of syphilis.

Character of Venereal Sores and Condition of Glands.

I conducted a close investigation at Cairo amongst 200 consecutive in-patients with venereal sores. The cases on discharge from hospital were kept under prolonged observation. There were 45 cases of syphilis—that is, a relative frequency of 3·5 non-infecting chancres (soft chancres) to 1 of syphilis.[22] Previous and present experience and carefully collected military statistics support this general average.

In 155 out of the above 200 cases the condition was conclusively demonstrated on clinical grounds to be non-infecting chancre (soft chancre). The chancre was not indurated and there were not any discretely enlarged and indurated glands in any of the cases. The lymphatic glands commonly suppurated and were operated on in 41 instances. In 36 out of the 45 cases of syphilis induration in the chancre was detected and the lymphatic glands were typical. Rash was later observed in 41 out of the 45 cases. I left the station before the remaining 4 cases had time to develop a rash, but all four had indurated chancres and discretely enlarged lymphatic glands. Pseudo-chancre induré only occurred twice amongst the 200 cases. There were 7 cases of phagedæna: 4 occurred in syphilis primary, and 3 in non-infecting chancre. The relative frequency, however, is of slight value in arriving at a correct diagnosis, the exact nature of the chancre and the condition of the adjacent lymphatic glands being of the utmost importance as regards diagnosis and treatment. In the foregoing investigation at Cairo, which I have since verified at Woolwich, and again at Malta, induration in some degree was almost invariably present at some time in syphilitic chancres, although it need not necessarily be obvious on the occasion or occasions on which the medical man happens to see the case, since it may have disappeared or may not have developed. The induration should be felt with the fingers. It is due to fibrous tissue with few vessels except on the surface. It is rapidly dissipated by adequate treatment with mercury or with potassium iodide, and is much more marked on the tense corona glandis. It is commonly less marked and frequently overlooked on the frænum. In the soft substance of the glans, or on the external skin of the penis it may be absent or not appreciable (parchment induration). On the glans a yellow film may form. Induration, with rare exceptions, occurred also in the proximal lymphatic glands in the primary stage, and these were bilaterally enlarged either shortly before or just as the rash came fully out. There was either a discrete bullety enlargement or hyperplastic non-suppurating mass, which rarely ended in suppuration in the case of syphilis, and the amygdaloid or bullet nature of the individual glands could be later made out as the mass slowly subsided under mercurial inunctions. These hyperplastic mattings in the groin usually resulted from concealment, irritation, and active exercise in the chancre stage, and such causes are apt to induce relapse in syphilitic chancres if the treatment is not sufficiently intensive to remove the induration. In the case of non-infecting sore, suppurating buboes rapidly resulted from concealment or neglect in the initial stages. The adjacent lymphatic glands in some instances may be slightly, temporarily, and painfully enlarged as the result of a non-infecting chancre or from other causes, but such glands commonly subside with rest. The glands in untreated or insufficiently treated syphilis, however, usually persist in despite of rest, become discretely larger, and are commonly painless. An increase of induration in the chancre, or the increasing anæmia of the patient in most untreated cases of syphilis will also put us on our guard until one or other of the classical symptoms of generalisation appears and finally clears the diagnosis.

Pseudo-chancre induré, first described by Professor Fournier in Paris, and also by Sir Jonathan Hutchinson in this country, is a condition where induration is stated to occur in a chancre which is non-syphilitic. The fact of the nearest lymphatic glands being normal will usually clear the diagnosis. It is feasible that in some instances such a condition may occur from reinfection in a person already the subject of constitutional syphilis, being, in fact, a local inflammatory reaction.

Various Points in Diagnosis.

Acquired syphilis on the genitals is nearly always accompanied by ulceration, and in certain phases of the ulcer it is quite impossible from the local appearance to diagnose syphilis. Induration may occur early or late in the base or edges of the ulcer, but when slight may escape our vigilance. In the case of artificially inoculated syphilis on the skin by

vaccination or otherwise, a papule is the usual initial lesion, and in rare instances I have seen such occur on the glans penis. The vast majority of syphilitic ulcers, however, probably come under the category of so-called "mixed" infections, in which the bacillus of Ducrey or other organisms exist simultaneously with the spirochæta pallida. The ulceration, purulent products, and, in phagedæna, the active necrosis or even sloughing of tissue, are mainly dependent on accidental factors, such as neglect, exercise, and the irritation of a tense prepuce. It can therefore be readily understood why suppurating buboes may occur in connexion with syphilis. Scars on the penis are very dangerous criteria on which to diagnose syphilis, as the largest scars are often due to loss of substance in a non-infecting chancre with phagedæna. Scars on the penis without any collateral evidence were formerly accepted as strongly suggestive of syphilis by writers on nervous diseases, but statistics compiled on such slender data should be rejected. Both non-infecting and infecting chancres may be indolent in healing, and the incidence of appearance after exposure to contagion is frequently a doubtful criterion on which to base a diagnosis, since truthful histories are hard to elicit and syphilitic chancres are commonly due to "mixed infections." The time limits were worked out many years ago on experimental or vaccinal inoculations, being 10 to 40 days, with an average of 25 days. Although a syphilitic chancre is in the large majority of instances single, yet the non-infecting variety of chancre also frequently appears single, more especially in hospital, where auto-inoculation has been prevented by aseptic or antiseptic treatment. Amongst patients presenting multiple sores, balanitic excoriations, or abrasions, one of these may later prove to be syphilitic, or a ring of induration may develop from the whole excoriated surface. Urethral chancres usually occur at the meatus with urethral discharge, and may prove to be erosive in nature; induration occurs in most cases as the ulcer heals, and both chains of inguinal glands are usually implicated. Erratic chancres are rare in England and usually syphilitic. In France, Germany, and Denmark extra-genital chancres are stated to occur in 5 per cent. of cases[23]; as far as army practice is concerned probably 1 per cent. The most common situations are the lip and tonsil. I have seen one, however, in the centre of the forehead, and one on the calf of the leg. The nearest lymphatic glands when the chancre is situated on the face are commonly ultra-typically enlarged.

Because a chancre is erratic it is not *ipso facto* syphilitic, although more commonly it is so. Non-infecting like syphilitic chancres may occur on any part of the body, and phagedæna may supervene in either. I have seen a non-infecting chancre on the finger and syphilis did not supervene (Case 8). Wax models of this condition are shown in the St. Louis Hospital Museum. There is also a specimen of a non-infecting ulcer in the groin in which phagedæna supervened. I have seen an unusually severe case of this condition which spread from the groin over the buttocks and between the legs—so-called "creeping bubo" of old works on surgery. They may spread all over the body. In the case in question the man was in hospital under observation over a year. The condition appeared at first sight to be a tertiary syphilitic ulceration in which phagedæna was occurring. There was, however, no clinical evidence of syphilis—the patient was about 20 years old—and syphilitic remedies were absolutely unavailing. The condition eventually resolved under local remedies and baths.

The period of time from contagion until generalisation occurs is a more or less constant factor. It is stated in the Regulations for Army Medical Services that after two months a case of "venereal sore" is to be diagnosed "soft chancre." If syphilis later occurs it will be dealt with as disease supervening. This point is one of great practical importance at the moment, more especially in the Services, because numerous persons have claimed to abort syphilis, and others have claimed to first cure and then re-inoculate it. From an army statistical point of view it would appear more rational to wait longer and definitely decide the diagnosis, as thereby one instead of two diseases is shown in the returns. The period of time, in my experience, in which generalisation takes place (as evidenced by rash or sore-throat) is 12 to 16 weeks from the date of contagion. The rash or other symptoms, as the result of treatment, may in some instances be latent and not be manifest for a longer period than four months, according to the intensive nature and value of particular forms of treatment. In other cases early syphilis may have been unrecognised and untreated, and mild varieties of rash may come and go in a few days. In such cases the patient commonly presents himself with intense general adenitis, albuminuria, iritis, or other severe manifestations of syphilis.

In conclusion, therefore, the diagnosis of early syphilis would not always appear to be as simple as many persons would have us believe. We naturally wish to prevent as far as possible the later occurrence of tertiary, malignant, and parasyphilitic conditions. In order to obviate these grave conditions it is requisite to both diagnose and treat syphilis early. Whatever each individual may think about the relative significance of Wassermann reactions, the fact must be admitted that in many instances we are as dependent to-day on a correct clinical interpretation of what we see as in the past when John Hunter wrote.

Remarks
ON
THE DIAGNOSIS AND TREATMENT OF URINARY TUBERCULOSIS.

Made before the Harveian Society on Oct. 26th, 1911.

By SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
PHYSICIAN AND LECTURER OF THE PRINCIPLES AND PRACTICE OF MEDICINE, ST. BARTHOLOMEW'S HOSPITAL; CONSULTING PHYSICIAN TO THE ROYAL FREE HOSPITAL, LONDON.

MR. PRESIDENT AND GENTLEMEN,—The title limits the scope of these remarks, the subject being not genito-urinary but urinary tuberculosis; that is to say, genital tuberculosis only comes into consideration so far as it may be the primary lesion and the cause of the urinary affection, and so becomes an aid to diagnosis. Acute tuberculosis of the urinary organs as a part of acute general tuberculosis need not be dealt with, for the signs of the local affection are lost amid those of the general infection. The subject therefore restricts itself to chronic tuberculosis of the kidney and its pelvis, of the ureter and bladder, for except as the result of direct extension from the prostate or bladder I do not know that tuberculosis of the urethra has been described.

MORBID ANATOMY.

It is well to start with the morbid anatomy of the condition, for the diagnosis rests largely upon the pathological data.

A few general propositions may be laid down: (1) That tuberculosis of the urinary organs tends to remain for a long time, or altogether, a local disease; (2) that it is generally a primary disease and but rarely the result of secondary infection from other parts; (3) that it is often bilateral, affecting the same parts on both sides, though not necessarily to the same degree; (4) that it may end, like all other forms of tuberculosis, in general infection—i.e., in acute general tuberculosis, but that this is not the usual mode of termination; (5) that the most destructive forms are the result of secondary infection with other organisms; (6) that the affection is commonest in young people; (7) that there is no marked difference between the sexes.

[The lecturer here showed in illustration the following series of specimens:—1. The left kidney converted almost entirely into caseous masses, but with practically no breaking down.

Such a kidney it might be thought would be best removed. So it might be if the other kidney had not been also seriously affected. The specimen showed how extensive the destruction of the kidney may be before life becomes impossible; in other words, how large a reserve in excess of what is absolutely required the kidneys possess. 2 and 3. Similar but less extensive disease in the kidneys. 4. The actual kidney here was not greatly damaged, but the pelvis was involved, and the case would probably have presented itself during life as one of pyonephrosis. 5. The lesion here was localised, being limited to the tip of one of the pyramids. 6 The origin of the ureter from the pelvis was involved. This would probably lead to obstruction and cause hydro- or pyo-nephrosis. 7. A tubercular tumour or mass as large as a walnut in the middle part of the ureter. This was, however, associated with tubercular lesions in both the kidney and bladder. 8. A bladder with tubercular ulceration at the mouth of the ureter. 9. A similar specimen with the disease at the neck or trigone. 10. A bladder in which the primary infection was in the kidney. 11 A similar specimen where the prostate and testicle were first involved. 12. A bladder with both ureters and kidneys exhibiting extensive tuberculosis throughout. Dr. West continued:—]

These specimens show that the infection of the urinary tract is not by extension from a tubercular focus near—e.g., a tubercular gland. It cannot be from without. Nothing then remains but that it must be through the blood. If so the question arises why it should locate itself as it does. It must be because the organ involved offers diminished resistance to the infection, and this may be due to previous disease or injury or to some other more obscure cause. In this relation it is interesting to know that it has been shown experimentally that when a part is injured and infective organisms injected into the blood, the infection may develop in the injured part only and nowhere else.

DIAGNOSIS.

The first symptoms that bring the patient under observation are usually (1) increased frequency of micturition; (2) occasional hæmaturia; and (3) pain, vesical or renal as the case may be.

The examination of the urine may show the presence of albumin and pus in varying amounts, and frequently associated with blood. Casts are not often found even in the renal cases. The amount of albumin is usually small and hardly more than the pus would account for. Pus may be present in very small amount, but in the renal cases the amount may be considerable.

The blood may be intimately mixed with the urine, giving it the usual smoky or dark colour, if the kidney be the seat of disease. If the blood comes from the bladder it is usually not intimately mixed with the urine, is brighter in colour, and often forms a definite deposit when the urine stands, the supernatant fluid containing little or none, and small clots may be present. If the tuberculosis involves the neck of the bladder, the urine first passed may be free from blood, the blood appearing at the end of micturition only, at which time pain is felt.

Pain may be very trifling or even altogether absent. It is most likely to be present when the lesion is on the neck of the bladder, and is then felt usually towards the end of micturition. When the lesion is in the pelvis of the kidney the pain is referred to the loin, and is probably due to some obstruction there which leads to temporary distension. If the distension be permanent and cause hydro- or pyo-nephrosis the pain may be considerable.

The cases fall into two clinical groups according as the symptoms are those of cystitis or pyelitis.

1. The symptoms of subacute cystitis of long standing in a young person would excite grave suspicion of tubercle. It would be necessary to exclude gonorrhœa and calculus as causes, and new growth too, though this would be unlikely. Tubercle would be almost certain if tuberculosis were found in the testicle, to which it might be secondary.

Bacteriological examination of the urine would then be made, and if the bacillus coli were absent tubercle only would remain; but, of course, tubercle could not be absolutely excluded if the bacillus coli were found, for there might be a double infection. Tubercle bacilli are often not easy to find in urine, even when centrifuged, and it is stated that they have been found in the urine of healthy persons. Of this I have no knowledge, and I am sceptical about it, for they may well be the smegma bacillus, which is also an acid-fast bacillus. If not discovered by direct examination the tubercle bacillus may be proved to be present by cultivation or by inoculation into guinea-pigs.

The general tuberculosis tests—e.g., von Pirquet or tuberculin—might be employed. If they yielded positive results they would merely show the presence of tubercle somewhere in the body and not necessarily in the urinary organs. The seat and extent of the tuberculosis could be investigated by the cystoscope.

The next question would be "Are the kidneys sound?" Tuberculosis of the bladder is rarely primary, and if there be no tubercle in the genital organs it would follow that presumably the kidneys were the seat of the primary mischief.

2. The kidney symptoms would be pain in the loin and tenderness on pressure, or a tumour which could be felt or demonstrated by the X rays. In this case, again, of course, calculus especially, and possibly new growth, would have to be excluded, as well as bacillus coli infection. If with symptoms of cystitis there be renal symptoms as well, the probability of the kidney being also tubercular is very great.

Where one kidney is affected the next question to be answered is whether the other kidney is sound; and this is of the greatest importance if surgical operation is contemplated. The use of the separator may be of some assistance here. Unfortunately, it may well be that the mischief in the second kidney may be so early or slight as to give little or no evidence of its presence. And even when the disease is advanced there may be little or nothing to show for it.

Tuberculosis of both kidney and bladder is quite compatible with good general health for a long time. Even symptoms may be absent till the pelvis of the kidney or the bladder becomes involved. This is perhaps the most important fact to remember in connexion with early tuberculosis of the urinary organs. When cystitis develops the health may suffer on account of the pain and frequency of micturition and the broken rest entailed. With pyelitis the hectic fever associated with suppuration will lead to great impairment of health; or the case may terminate more or less suddenly with the signs of general pyæmia or uræmia or of general tuberculosis.

TREATMENT.

The *cystitis* must be treated, of course, on general lines—by rest, urinary sedatives, and washing out if necessary. I do not think any surgical operation on the bladder holds out promise of cure. It could only be recommended as a palliative measure for the relief of symptoms. Tuberculin injections, whether of old or new tuberculin, or of bovine tuberculin, have not in my experience proved to be of much value. At any rate, I have not been able to convince myself that the cases have done better with this treatment than they would have done without. Still, good results have been recorded sufficiently often to encourage the hope that in the future it may be attended with greater success and I should use tuberculin injections as an adjuvant. It is, however, possible to do harm with them and to kindle into activity a lesion which was at the time quiescent. It is very doubtful whether the very small doses have any or much demonstrable effect upon the course of the disease, while large doses may certainly do mischief.

The treatment of severe *pyelitis* must be almost entirely surgical. To open and drain the kidney is a simple operation, but except as a palliative measure is not desirable, for the sinus will not heal, may itself become tubercular, and secondary infection is likely to occur, which may seriously aggravate the patient's condition.

The fact that tuberculosis of the kidney remains for so long a local disease naturally raises the hope that removal of the diseased kidney may effect a cure. Unfortunately, the other kidney is frequently affected too, and it is most difficult, if not impossible, to be ever moderately certain that the other kidney is sound.

To remove a kidney, though the mere operation may be not difficult, is in itself a grave procedure, for it at once deprives the patient of one-half of the total stock of a gland which is essential to life. It is true that there is a great reserve of kidney substance in the healthy body. Yet it is also true

that the reserve is not unlimited. Two-thirds of the kidney substance may be destroyed before the limit is reached—that is to say, that men can live so long as they have one-third of the kidney substance still in functional activity. If, then, one kidney be completely destroyed or removed, two-thirds of the other kidney must still be active if life is to be maintained; in other words, if one-third of one kidney be diseased the removal of the other one would be followed by the patient's death.

Even in a very diseased kidney portions of it may still be doing useful work, and this, little as it may be, may be just the amount necessary in conjunction with the other kidney to ward off grave symptoms of renal inadequacy.

To remove a tuberculous kidney requires, then, the most serious consideration, and cannot fail to be attended with serious risk. If the other kidney is presumably tuberculous too, the case is, I think, practically unsuitable for such an operation.

Tuberculous disease of the kidney may, it is true, be unilateral, but as a rule only in the very early stages, and then the diagnosis is so difficult; but even in quite early stages post-mortem evidence proves that both sides may be affected, though clinical proof of it be lacking.

When the disease in one kidney is advanced enough to be capable of certain diagnosis, the chances of the other kidney being affected too are very considerable, and the removal of a kidney then would be only palliative treatment and not likely to lead to cure.

Again, when the bladder is also tubercular, removal of one kidney would not cure the bladder nor prevent secondary infection of the other kidney even if it had been free of disease at the time of operation.

Removal of the kidney would thus seem to be reserved especially for those cases in which the tubercular disease is strictly limited to one kidney, and then the diagnosis is rarely made early enough.

All that I wish now to do is to protest against regarding the removal of a tubercular kidney as an operation to be lightly decided on. It is a very grave act, requiring the most serious consideration and in all cases involving grave risks. The very ease and success with which the mere operation can now be done renders this caution, I think, the more necessary. The question is not whether the operation can be safely and successfully done, but what will be the condition of the patient afterwards, and how far his chances of life will be altered for better or worse.

WASSERMANN REACTION IN GENERAL PARALYSIS.

THE CONTROL OF A SERIES OF WASSERMANN REACTIONS IN CASES OF GENERAL PARALYSIS BY POST-MORTEM EXAMINATION.

BY J. P. CANDLER, M.A., M.D. CANTAB., D.P.H.

(*From the Pathological Laboratory of the London County Asylums.*)

TWO years have now elapsed since the publication of a joint paper in the *British Medical Journal* with Dr. Henderson Smith of the Lister Institute; in this paper statistics were given on the result of a series of Wassermann reactions on the cerebro-spinal fluid, and (in a few instances) on the blood serum of cases of general paralysis of the insane, and of other forms of insanity as controls. A considerable number of the cases having now died Dr. F. W. Mott has suggested that the practical value of the reaction should be critically tested by comparison of the results obtained, with the ultimate diagnosis post mortem.

For the purpose of this test only those cases have been considered in which the cerebro-spinal fluid was withdrawn during life, and in which the clinical diagnosis has been controlled by post-mortem observation, including in the majority of cases, and always in a doubtful case, the microscopic examination of the cerebral cortex. I may here mention that Dr. Mott has been kind enough to examine and give his opinion on the sections of all the doubtful cases. The greater number of the cases comprise those which furnished the data for the previous paper; the reactions on the fluids of the rest of the cases have been performed at the Pathological Laboratory at Claybury Asylum.

The list is far from being comprehensive, for a large number of cases have recently been examined at the Claybury Laboratory, but are still living; and although the analysis of the Wassermann test on these cases would give practically identical results with those now recorded, they fail to fulfil the conditions required for the paper—namely, that the final appeal should rest with the post-mortem findings. There are, however, among these cases several which possess some points of interest to which attention should be directed. In addition, a considerable number of fluids have been examined which were only withdrawn and tested after death. These have also been excluded from the list.

Results of Wassermann Reaction.

In 80 cases in which the cerebro-spinal fluid was withdrawn during life by lumbar puncture and examined by the Wassermann test, clinical diagnosis has been controlled by post-mortem examination. Of this number 67 cases gave a positive Wassermann reaction during life, and all of these showed at death the characteristic changes of general paralysis. Of the remaining cases which gave negative results 2 were found at necropsy to be cases of general paralysis. The Wassermann reaction, therefore, failed in only 2 cases out of 80 (i.e., in just under 3 per cent.), and in both cases only one examination of the fluid during life was made; the percentage incidence, therefore, of positive results in cases of general paralysis = 97 per cent. In a few instances the blood serum also was examined, and was positive in every case of general paralysis of the insane.

With regard to the two cases of general paralysis in which the result of the Wassermann test was negative during life, one of the cases was commented on in the previous paper. The cerebro-spinal fluid gave a negative reaction two months before death—the first time it was tested. The blood serum was examined three days before death and gave a positive reaction, and both cerebro-spinal fluid and blood serum withdrawn after death gave a positive reaction. A cytological count on the cerebro-spinal fluid was not made. The second case was punctured once only, three months before death. The Wassermann reaction was negative; a cytological count showed a slight excess of lymphocytes. Clinically the case was looked upon as one of general paralysis, and this diagnosis was confirmed at necropsy.

Among the other cases which gave a negative reaction and have died there are six which require special notice, inasmuch as they were considered to be either certain or suspected cases of general paralysis.

TABLE I.—*Negative Wassermann Reactions Confirmed by Necropsy.*

—	—	Form of mental disorder.	Wassermann result.	Post-mortem macroscopic and microscopic appearances.
1	M.	General paralysis.	—	Not general paralysis.
2	M.	Acute mania; general paralysis ?	—	,, ,, ,,
3	M.	General paralysis.	—	,, ,, ,,
4	M.	Mania; general paralysis ?	—	,, ,, ,,
5	M.	Acute mania; general paralysis ?	—	,, ,, ,,
6	M.	General paralysis.	—	,, ,, ,,

CASE 1.—Male, aged 37. Length of stay in asylum, two months. Diagnosis on admission, general paralysis. History prior to admission: Patient had led a steady life; he was easily worried; he had suffered a long time from violent occipital headaches. There was a family history of phthisis; one of his sisters was an inmate of Brookwood Asylum. On admission: Patient was rambling and incoherent in conversation; his pupils reacted; the knee-jerks were present. Six days later: Speech was tremulous and uncertain; he complained of headache and confusion; he was restless and talkative and did not know where he was. He was somewhat grandiose about his own and his wife's means. His pupils were stated to be inactive to light and unequal.

Lumbar puncture was performed three weeks before death. The Wassermann reaction was negative. There was some excess of lymphocytes in the cerebro-spinal fluid.

Necropsy.—Post mortem the brain showed no changes to the naked eye suggestive of general paralysis. The membranes were not thickened, and there was an absence of vascular congestion. There was no excess of fluid, and the brain showed little or no evidence of wasting; there were no granulations either in the lateral ventricles of the brain or on the floor of the fourth ventricle. The brain was small in size; of a total weight of 1150 grammes; the weight of the pons and cerebellum alone was

710 grammes. As the weight of the pons and cerebellum is approximately one-eighth of the total brain weight this brain showed a congenital deficiency of weight of the cerebral hemispheres of about 210 grammes, which in the absence of any evidence of cortical wasting was probably due to a cerebral under-development. This is further supported by the microscopic appearances.

Microscopic characters of the cerebral cortex.—There was a complete absence of the changes usually found in general paralysis. There was no increased vascularity of the cortex, no infiltration of the vessels with plasma cells or lymphocytes. There was absence of "rod cells" (Stäbchenzellen), isolated elongated cells first described by Alzheimer in cases of general paralysis. There was an absence of neuroglial proliferation. Some of the ganglion cells of the cortex showed degenerative changes, others were fairly normal in appearance. There was, in fact, an absence of the widespread degeneration usually seen in general paralysis. There was a slight amount of lymphocytic proliferation of the meninges, due probably to a terminal meningeal inflammation.

Dr. Mott, after seeing the sections, was of the opinion that the case was one of insanity associated with cerebral under-development, and was certainly not a case of general paralysis. The microscopic appearances were, he thought, very similar to those observed in a case of congenital imbecility recently under his notice, of which the following are brief case-notes:—

Congenital imbecility.—Female, aged 21. Length of stay in asylum was four years. Diagnosis on admission was congenital imbecility. She was stated to be simple and childish; her gait was steady. The pupils reacted to light; the knee-jerks were present. She gradually became more demented and quite helpless. About three months before death she was considered to be a case of general paralysis. She was then very demented and able to answer only the simplest questions. Death ensued from tuberculous broncho-pneumonia. The Wassermann reaction on the cerebro-spinal fluid removed after death was negative.

Dr. Mott, at the post-mortem examination, thought the case might be one of juvenile general paralysis, but a microscopic examination proved that this was not the case.

CASE 2.—Male, aged 50. Length of stay in asylum, 19 months. Diagnosis on admission, acute mania; ? general paralysis. This patient had previously been in an asylum in India. He had another attack in Melbourne 15 years afterwards. He was stated to have been a man of temperate habits, and no cause was known to account for his mental condition. Condition on admission: The tongue was furred; pulse rapid and of high tension. Pupils large; reacted sluggishly. Reflexes normal. Speech and reaction quick; attention feeble; memory fair. He had delusions of grandeur, suspicion, persecution, and exaltation. Three weeks after admission he had considerably improved and was quiet and fairly coherent. He still had troubles of persecution and his facial muscles were tremulous.

Lumbar puncture was performed four months before death. The Wassermann reaction was negative and no lymphocytes were found in the centrifuged deposit of the cerebro-spinal fluid. The cause of death was capillary bronchitis and broncho-pneumonia.

The macroscopic and microscopic appearances of the brain showed no evidence of general paralysis.

CASE 3.—Male, aged 49. Length of stay in asylum, 2 years and 4 months. Lumbar puncture was performed 15 months before death. A negative Wassermann reaction was obtained. There were a very few cells in the centrifuged deposit of the cerebro-spinal fluid.

This man was looked upon as a general paralytic on admission, and, in fact, right up to death. The notes mention, however, that in 1880–81 he had been in Hamburg Hospital for four months with right-sided hemiplegia and motor aphasia. He is stated on admission to imagine that he is possessed of immense wealth. Tongue tremulous. Pupils, left larger than right; both react well to light and accommodation. Knee-jerks increased on the right side, but absent on the left. He reacts to questions fairly well, but is rather confused. He is grandiose in manner. He acknowledges to an attack of syphilis 20 years ago. He died from the effects of carcinoma of the tongue with secondary malignant infiltration of the lungs.

Necropsy.—At the post-mortem examination the brain of this patient showed none of the naked-eye changes characteristic of general paralysis. There was, however, considerable atheroma of the vessels at the base of the brain, and also in the aorta and coronary arteries. The kidneys were fibrotic. A microscopic examination of the brain showed none of the characteristic changes of general paralysis, but the vessels of the meninges and of the grey matter of the cortex stood out firmly; there was a general thickening of the coats, and in several places there had occurred hæmorrhages into the sheath of the vessels.

The case, therefore, proved to be one of thickening and sclerosis of the cerebral vessels, probably the result of previous syphilitic infection resulting in organic dementia.

CASE 4.—Male, aged 37. Length of stay in asylum, 1 year and 5 months. Diagnosis on admission, mania, ? general paralysis. On admission the notes state: "Tongue tremulous. Pupils dilated; react sluggishly to light; both react to accommodation. Knee-jerks exaggerated. Is simple and childish in his manner and behaviour; laughs irrelevantly, and seems not to realise his position, which ought to impress him more than normally as he has been a clerk under the Metropolitan Asylums Board for many years." A note made four days later states that his pupils were unequal and were both inactive to light. He had morbus cordis with loud systolic murmur. The patient remained in much the same mental state, being rambling during a conversation and the subject of auditory hallucinations. Death was due to lobar pneumonia.

Lumbar puncture was performed a week after admission, and again about three weeks later. On both occasions the fluid was negative.

Necropsy.—Post mortem there was nothing macroscopically or microscopically to indicate general paralysis of the insane.

CASE 5.—Male, aged 50. Length of stay in asylum, 5 months. Diagnosis on admission, acute mania, ? general paralysis. Condition on admission: A poorly nourished man with a sallow complexion; double arcus senilis, and atheromatous arteries. Admitted in a state of great excitement and under restraint. Knee-jerks exaggerated; pupils somewhat contracted; no reaction to light. Hallucinations of sight and hearing. He was rather on grandiose terms with himself and his speech was shaky. He had no knowledge of time or place. Three months later the notes stated that he was still dull and confused, and his memory was impaired. The pupils were unequal and reacted only sluggishly to light. The knee-jerks were exaggerated. Immediately prior to death he developed râles over both lungs. He had two convulsive attacks, the latter being attended with temporary paralysis of the left arm.

Lumbar puncture was performed three months before death. The Wassermann reaction was negative, and there were no cells in the centrifuged deposit of the cerebro-spinal fluid.

Necropsy.—Post mortem there were marked arcus senilis and atheroma of the cerebral arteries and of the aorta and coronary arteries. The kidneys were granular; the lungs broncho-pneumonic. Neither the macroscopic nor microscopic appearances of the brain were at all suggestive of general paralysis.

CASE 6.—Male. This case was diagnosed as general paralysis. The Wassermann reaction on the cerebro-spinal fluid was negative. Post mortem he was found not to be a case of general paralysis, but of organic brain disease (arterio-sclerosis, softening of the brain, and cerebral hæmorrhage).

Among the cases which gave a negative reaction there were some who were looked on as either certain or suspected cases of general paralysis. Although they are still living, I think that a table showing the clinical diagnosis at the time of puncture, together with the present condition, would be of interest.

TABLE II.—*Negative Wassermann Reaction Confirmed by Subsequent Diagnosis.*

No.	Sex.	Date of puncture.	Wassermann.	Clinical diagnosis at time of puncture.	Result and final diagnosis.
1	M.	1/2/09.	—	? General paralysis. ? Organic brain disease. (Head injury.)	Confusional insanity. Discharged 22/2/09.
2	M.	1/2/09.	—	? General paralysis.	Alcoholic mania. Discharged 19/3/09.
3	M.	20/6/09.	—	? "	Confusional insanity (alcoholic). Discharged 6/8/09.
4	M.	20/6/09.	—	General paralysis.	Dementia præcox.
5	M.	20/6/09.	—	Strong suspect, general paralysis.	Mania (alcoholic). Discharged 22/1/10.
6	M.	20/6/09.	—	General paralysis.	Delusional insanity.

It will be seen from this table that 4 out of the 6 cases have been discharged from the asylum, and in every case the original diagnosis has been subject to alteration. These results, then, show that a negative Wassermann reaction may be of considerable value in cases of doubt, and is not to be regarded as valueless, as some maintain. To be of real value, however, a negative result should be confirmed by another examination of the fluid. The result of the reaction of the blood serum in cases in which the cerebro-spinal fluid is negative may be of further considerable aid in arriving at a correct diagnosis.

Observations on the Results Obtained.

A comparison of the percentage of positive reactions on the cerebro-spinal fluid of cases of general paralysis recorded in this paper with those obtained by other observers shows that they are in close agreement. Marie, Levaditi, and Yamanouchi have obtained a positive reaction with the cerebro-spinal fluid in 93 per cent.; Raviat, Breton, and Petit, 93 per cent.; Morgenroth and Stertz, 100 per cent. Plaut, out of 147 cases, obtained a positive reaction in 139, doubtful reactions in 2, and negative in 6.

Schölberg and Goodall tested the sera of 49 cases of general paralysis, and obtained a positive result in only 75·50 per cent., and with the cerebro-spinal fluid of 41 cases the percentage of positive results was 41·46. It is impossible to account for the extremely low percentage obtained by these observers. It is certainly not due to the precaution taken to eliminate the personal equation.

Max Nonne has mentioned a point of great importance in the performance of the test—namely, that even when the original method is employed the failure to obtain a positive result may be due solely to the employment of too little of the cerebro-spinal fluid. He states that as much as 1 c.c. can be taken without any fear that a positive reaction will be given in a non-specific case. In support of this statement I may mention that in a case of general paralysis recently examined, and in which the diagnosis was confirmed post mortem, total prevention was obtained with 0·8 c.c. of cerebro-spinal fluid, but there was complete hæmolysis with

0·5 c.c., which shows at once that the case would have been missed if the larger amount had not been taken.

At Claybury we constantly use 0·8 c.c. of cerebro-spinal fluid as one of our dilutions in a total volume of 3 c.c., and so far as we are aware we have not met with a positive result in any case apart from general paralysis. The need, therefore, of using comparatively large doses of cerebro-spinal fluid is further proof of the necessity of employing the original Wassermann reaction instead of the various modifications which have been devised, especially those which employ only infinitesimal quantities of reagents.

Apart, however, from those cases which may possibly be missed by the employment of insufficient doses of cerebro-spinal fluid, there remains the small percentage which fail completely to give the reaction. The reason for this is not yet understood. They are not confined to cases of incipient general paralysis; the reaction may fail in advanced and rapidly progressive cases; it is also said to be absent in some cases where the disease is stationary, and in remissions. This negative phase is stated to be often replaced by a positive one, and hence the necessity of recognising the importance of another examination of the fluid at a later date.

The Examination of the Blood Serum in Cases of General Paralysis.

The number of cases in our series in which the blood serum has been examined, as well as the cerebro-spinal fluid, is too small to be of statistical value. In every instance, however, in which the cerebro-spinal fluid gave a positive reaction the serum gave a similar result.

Marie, Levaditi, and Yamanouchi in an early paper recorded only 59 per cent. of positive results with the blood serum of general paralytics. Plaut, however, examined the cerebro-spinal fluid and blood serum of 147 cases of general paralysis; the reaction was doubtful or negative in the cerebro-spinal fluid of 8 of these cases, but the blood serum was positive with every case. His opinion is that the blood serum gives a more delicate and more constant reaction in cases of general paralysis than does the cerebro-spinal fluid. His results have recently been confirmed by Boas of Copenhagen, who has obtained a positive reaction with the serum in each of 139 cases of dementia paralytica.

The Wassermann Reaction in Cerebral Syphilis.

Two cases only of syphilitic affection of the central nervous system have come under our notice. In both cases a negative Wassermann reaction was obtained with the cerebro-spinal fluid. Plaut in his monograph records the result of the examination of the cerebro-spinal fluid and of the serum in 20 cases. The cerebro-spinal fluid gave a negative reaction in 17 and a positive in 3 (i.e., a negative reaction in 83 per cent. of the cases). The serum gave a negative reaction in 1 and a positive in 19 Marie, Levaditi, and Yamanouchi in 6 supposed cases of cerebral syphilis found the cerebro-spinal fluid to be negative in 5 and positive in 1; of the sera, 3 were positive and 3 negative.

Frenkel and Heider in 7 cases found the cerebro-spinal fluid gave a negative reaction in 5 and positive in 2. Forster in 4 cases found the cerebro-spinal fluid negative in 3 cases and weakly positive in 1. Stertz found the cerebro-spinal fluid negative in 8 cases examined.

It may therefore be taken that, as a rule, the reaction in syphilis of the central nervous system is positive with the serum and negative with the cerebro-spinal fluid.

The Cytological Examination of the Cerebro spinal Fluid.

In the majority of the cases recorded a cytological examination was made of the cerebro-spinal fluid. In all the cases of general paralysis so examined lymphocytes and plasma cells were found in pathological excess. In one case, which microscopically was proved to be a case of general paralysis, a slight increase in lymphocytes was observed; and also in one case of general paralysis, in which a negative Wassermann reaction was obtained, there was a slight increase in cells, but hardly sufficient to be considered a pathological excess. It has been shown by Plaut and others that the number of cells in the fluid bears no relation to the intensity of the reaction. Cases of general paralysis may be found in which the Wassermann reaction is strongly positive, but no cells are present, and the reverse may also occur. A similar condition may be met with in syphilis of the nervous system. Plaut has shown that there may be an excess of lymphocytes in cases of secondary and tertiary syphilis without any involvement of the nervous system.

Mononuclear cells in excess may be found in Landry's paralysis and in herpes zoster. The presence of mononuclear cells in the cerebro-spinal fluid is therefore in no wise specific of general paralysis or of syphilis of the nervous system. Moreover, in both these diseases they are liable to variations. The rule, however, is that lymphocytes and plasma cells are found in excess in both general paralysis and syphilis of the central nervous system.

Value of the Wassermann Reaction.

From what has been said it is clear that the correct interpretation of the Wassermann reaction on the cerebro-spinal fluid can only be arrived at after careful consideration of the clinical symptoms, together with a Wassermann reaction on the blood and a cytological examination of the cerebro-spinal fluid. Used in this manner and with due regard for the few anomalous reactions which may occur it is certain that the reaction is one of the most reliable and valuable tests for general paralysis that we have. In fact, it is, in the opinion of many, a more reliable test than is the Widal for typhoid fever. Not only will it determine 90 per cent. of cases of general paralysis, but it will if used properly help to clear up the diagnosis in cases of alcoholic insanity, polyneuritic mental psychoses, neurasthenia, cerebral tumour, and other conditions which may in a few of their features simulate general paralysis. It is certain to be largely employed in the future in medico-legal cases to decide how far syphilis has been responsible for cases of insanity following on head or other injuries.

The differential diagnosis between general paralysis and syphilis of the central nervous system may sometimes be extremely difficult, but considerable assistance can be obtained by a study of the Wassermann reaction and cytological count on the cerebro-spinal fluid to which allusion has already been made. A positive reaction in the blood serum means no more than that the person has had syphilis. It is not diagnostic of general paralysis or of cerebral syphilis. A negative reaction with the serum, according to Plaut and Boas, practically dismisses the possibility of active syphilitic or parasyphilitic affections. The practical advantage of this is that in cases where it is not advisable to resort to lumbar puncture an examination of the blood serum alone will often be of material assistance. If a negative result is obtained it may save the necessity for lumbar puncture; a positive result in a patient suffering from nervous or mental disease, however, makes the examination of the cerebro-spinal fluid more necessary than ever.

It is of very great importance to remember that the accidental contamination of the cerebro-spinal fluid with blood in a case of a person suffering from syphilis may lead to a wrong diagnosis of general paralysis, due simply to the fact that a sufficient amount of the serum has become mixed with the cerebro-spinal fluid to give a positive Wassermann reaction on the fluid. The following instance affords a very good practical illustration of this.

A female, aged 63. Mental condition, dementia (? alcoholic). Patient died rather suddenly. The cause of death, ascertained post mortem, was the rupture of an aneurysm of the aorta into the thorax. The whole of the aorta and cerebral vessels were markedly atheromatous, with numerous plaques of pearly white fibrosis, undoubtedly syphilitic. There was no evidence of general paralysis or syphilitic brain disease. The ovaries were scarred and there was a chronic adhesive salpingitis and parametritis. The blood serum (removed post mortem) gave a marked positive Wassermann reaction. The cerebro-spinal fluid, also withdrawn after death, was mixed with some blood; this, too, gave a positive Wassermann reaction, but much less marked and almost certainly due exclusively to the presence of the blood serum in the fluid.

Description of the Method Employed.

The method employed throughout the work, both at the Lister Institute and at the Pathological Laboratory at Claybury Asylum, has been that used by Wassermann. General experience has shown that this method is by far the most reliable, and admits of more accurate standardisation than do any of the labour-saving modifications which have been suggested as substitutes for the original method.

The technique used in the laboratory at Claybury is practically identical with that described in the previous paper written in collaboration with Dr. Henderson Smith. For hæmolysin we have used, in the majority of cases, the serum of a rabbit immunised against ox corpuscles. This was supplied to us by the Lister Institute and has been in our possession for close on two years. It has been kept in sealed tubes in the cold chamber, and during this time its

titre has remained practically constant. In a few cases we have used rabbit's serum immunised against sheep's corpuscles when ox blood was not available (this was also kindly supplied by the Lister Institute).

For complement we have used the serum of the guinea-pig. The animal has been killed over-night and the clear serum collected the following morning after a night's sojourn in the cold chamber. For artificial antigen we have invariably made use of the liver of a syphilitic fœtus. Experience has shown that the success of the test depends almost completely upon the use of a good extract, and on repeated standardisation of all the reagents employed, so as to detect and make correction for any possible variations which may occur.

Carl Browning, Ivy McKenzie, H. R. Dean, D'Este Emery, and others have shown that liver extract is able of itself to absorb complement, and that the amount of complement capable of absorption varies with each individual extract, and also is liable to variation in the same extract. An artificial antigen must contain a sufficient quantity of lipoids, and these lipoids are apparently in an easily dissociable condition, for the addition of a drop of a solution of iodine and potassium iodide demonstrates the presence of choline or a similar substance, and also a film prepared from the extract readily takes the Scharlach stain. The suitability of an extract to act as an artificial antigen depends very materially upon its methods of preparation. This has long been recognised in the laboratory at Claybury Asylum, and various methods have been used in order to obtain a clean extract of the liver. These methods have been recently corroborated by Noguchi, who has shown that the liver extract prepared in the ordinary way (i.e., by simple watery or alcoholic extraction), besides containing the "antigen" proper, may contain in addition bodies possessing hæmolytic and anti-complementary properties. In the process of extraction, therefore, these substances must be eliminated as far as possible.

The method employed in the laboratory is as follows. The weighed liver of a syphilitic fœtus is ground up with a sufficient quantity of silver sand and plaster-of-Paris so that after a few hours it can be reduced to a powder. The use of gypsum has been adopted in order to obtain an anhydrous residue, from which salts, jecorin, and other constituents of the liver cannot be extracted with cold alcohol. Latterly we have adopted the procedure of washing this powdered residue with acetone previous to the extraction with cold alcohol. This acetone washing removes from the mass bodies which have anti-complementary and hæmolytic properties. The ground-up liver is allowed to dry at room temperature. The dry residue is transferred to a flask and sufficient quantity of alcohol added. The flask is put aside at room temperature for two or three days. The alcoholic extract is then filtered off and the filtrate made up with washings with alcohol, so that 4 c.c. is equivalent to 1 gramme of liver. In this way lecithin and other phosphatids which are most suitable as antigens are best extracted. Liver extract so prepared we have found to act uniformly in a 1 in 5 saline dilution, and also to keep for months without much alteration if suitably stored. Our extracts are stored in the cold chamber in dark bottles.

In performance of the test an approximation of the intensity of the complement absorption has been obtained by keeping the quantities of complement, liver extract, and sensitised blood cells constant and introducing falling doses of cerebro-spinal fluid or serum, positive and negative controls being put up at the same time. The preliminary standardisation of the minimum hæmolytic dose of the immune body was never neglected, and thrice this quantity was invariably used. It may be here mentioned that these quantities have remained remarkably constant. The dilutions of the cerebro-spinal fluid have been so arranged that with a negative fluid hæmolysis has occurred in every tube without exception, while in cases of general paralysis prevention occurred in all or most of the series of tubes.

It has only been by very careful observation of the strength of the liver extract that so definite a reaction has been obtained, so that any absorption of complement brought about by the liver extract alone should be insufficient to affect the series. All tests have been fully controlled, and in view of the intricacies of the reaction we consider this procedure to be absolutely essential.

Summary.

A positive Wassermann reaction was obtained with the cerebro-spinal fluid of 67 out of 69 cases of general paralysis of the insane (a percentage incidence of positive reactions of 97 per cent.).

In only two cases of general paralysis did the cerebro-spinal fluid fail to give a positive reaction before death. In one of the cases the cerebro-spinal fluid was negative two months before death, but positive after death. The blood serum of this patient tested three days before death gave a positive reaction. In the second case the cerebro-spinal fluid gave a negative reaction three months before death. This was the only occasion on which the fluid was examined.

Six cases of suspected general paralysis in which the Wassermann reaction was negative have died, and have been proved by post-mortem examination and careful microscopic investigation not to have been cases of general paralysis. Of 6 other cases of suspected general paralysis the cerebro-spinal fluids of which gave a negative reaction, 4 have been discharged from the asylum, and in all the original diagnosis has been altered.

The reaction cannot be obtained in the cerebro-spinal fluid of any other forms of insanity, except in a few rare cases of syphilis of the central nervous system.

In all cases an excess of lymphocytes in the cerebro-spinal fluid indicates organic disease, but not necessarily either syphilis or parasyphilis.

A positive reaction with the cerebro-spinal fluid, in conjunction with lymphocytosis, points much more strongly to parasyphilis, especially general paralysis, than to cerebral or spinal syphilis.

Every case of general paralysis is said to give a positive serum reaction, but a positive serum reaction merely indicates that the patient has had syphilis. Consequently, if there is a positive serum reaction, associated with nervous or mental phenomena, lumbar puncture should be performed, and if the cerebro-spinal fluid gives a positive reaction the indication is strongly in favour of general paralysis.

It is advisable if a negative reaction is obtained in the fluid, and there are other indications pointing to the possibility of general paralysis in the pre-paralytic stage, to make another puncture at a subsequent date and examine the fluid.

Although many modifications and simplifications of the Wassermann method have been introduced, in view of the importance of this test from the medico-legal point of view, it is highly desirable to use the most reliable method. Many of these modifications fail by giving positive results when the original method would give a negative.

The only modification of the original Wassermann method we have used lies in the preparation of the liver extract, whereby substances which adversely influence the reaction are eliminated. The liver is reduced to an anhydrous powder by mixture with plaster-of-Paris and silver sand; it is then washed with acetone, and finally extracted with cold alcohol.

I wish to express my thanks to Dr. Mott for his kindness in examining the microscopic sections, and also for his advice throughout the work; and to Mr. Sydney Mann for the chemical work in the preparation of the liver extracts, and for his assistance with the tests conducted in the laboratory.

ON AN EPIDEMIC OF CONJUNCTIVITIS

ASSOCIATED WITH THE PRESENCE OF A GRAM-POSITIVE DIPLOCOCCUS RESEMBLING, BUT DISTINCT FROM, THE PNEUMOCOCCUS.

BY J. P. McGOWAN, M.A., M.D., B.Sc. EDIN.,
BACTERIOLOGIST TO THE ROYAL COLLEGE OF PHYSICIANS' LABORATORY, EDINBURGH;
AND
W. MACRAE TAYLOR, M.B. EDIN., F.R.C.S. EDIN.
(From the Royal College of Physicians' Laboratory, Edinburgh.)

THE following paper deals with an epidemic of conjunctivitis in an institution, and the facts are considered worthy of record, in the first place, because the outbreak was associated with the presence of an organism which, we believe, has not previously been described; and, secondly, because of the liability of this organism to be confused with the pneumococcus in a superficial[1] examination, such as is generally employed in ophthalmic practice.

Clinical Notes.

At a preparatory boarding school for boys (with about 100 pupils, aged from 8 to 14 years) in the country, an epidemic of mild ophthalmia occurred in the spring, presenting some unusual features, chiefly bacteriological.

Three of the boys, who were brothers, were allowed to leave school on a Saturday in order to attend the marriage of a sister at a considerable distance from the school. On the following Monday one of them developed ophthalmia, but he seemed to be better on the Tuesday, and on the Wednesday he was apparently quite well. On that day he returned to school with his two brothers, and on the following Monday (Feb. 27th) one of the brothers and also another boy in a different form, and in no way intimately connected with the three brothers, developed ophthalmia. On Feb. 28th these two boys and another boy had ophthalmia, and the original boy, who had been affected while he was away, had a slight relapse.

On March 3rd there was a fresh case; on the 6th there were three fresh cases; on the 7th two; on the 8th one; and so on until, on April 4th, the forty-ninth, and last, case was the eldest of the three boys who had gone to the wedding.

It should here be noted that all the cases were isolated from the very beginning, as soon as any signs of irritation were observed. In most of them the treatment consisted in the application of 20 per cent. argyrol once a day, which, after half an hour, was washed away with boric solution; irrigation with boric solution three or four times a day, and paroleine was applied. The boys were kept in darkened rooms and were not allowed to use their eyes. In 9 out of the 49 cases a relapse occurred—generally ten days to a fortnight from the commencement of the disease. As a rule, the duration of the inflammation was short—from two to five days. Some of the cases were considerably longer in duration, but in none of them did the condition lead to any serious complication or inconvenience at all. The characters of the affection were those of a simple conjunctivitis. Beginning in one eye it usually spread to the other. There was injection of the vessels of the orbital and palpebral conjunctiva, particularly of the lower eyelid; very little œdema; only slight purulent exudation and some photophobia; very little headache or tenderness of the eyes.

The mode of propagation was difficult to ascertain. All the boys have separate towels, but in the "change room" which is used after games there are roller towels which are made use of by several boys.

The occurrence of ophthalmia in a boys' school is, of course, very usual, but this epidemic was distinguished by two features: first, the mildness of the cases, and, secondly, the extent to which the epidemic spread, practically half of the boys in the school being affected.

The only other cases in the school, besides those of the boys, were a table-maid in the headmaster's private house, who began to be affected on March 12th, and who had a relapse on the 23rd, and one maid who was in attendance on the boys and constantly amongst them, who became affected on March 17th. It is interesting also to note that the mother of the three boys who attended the wedding suffered from the affection a week after the first boy became ill. It should be mentioned that there was no other illness in the school at the time.

Bacteriology.

General.—The organism, to be afterwards described, was obtained in pure culture from the conjunctival sacs of all the cases that were examined—five in number. The cultures from these cases were made on blood agar, and the appearance of the colonies after 24 hours' incubation at 37° C. was identical, as far as one could tell, with the appearance that the pneumococcus produces—namely, fine, discrete dewdrops.

In films made directly from the conjunctival secretion, which was very scanty, the organism appeared as a Gram-positive diplococcus, whose elements were elongated and in some instances typically lancet-shaped. As regards the presence or absence of capsules in the organism in the secretion it was difficult to be certain, one reason being that the organisms were few in number. Even supposing the capsules were absent,[2] this in no way lessens the liability to confusion with the pneumococcus, for with undoubted pneumococci in the sputum capsules are often not demonstrable even by methods specially suitable for the purpose. As mentioned above, the secretion was scanty and the organisms were few in number in it. This is noteworthy, as in the epidemics of pneumococcal conjunctivitis recorded in the literature the secretion is usually said to be copious and the organisms abundant.

Cultural characteristics.—The organism grows well on blood agar at 37° C. On gelatine at 18° C. it does not grow. There is no growth on potato at 37° C. It grows well on inspissated blood serum at 37° C. Litmus milk incubated at 37° C. is usually unchanged; sometimes a little acid is formed after a long time but never any clot.

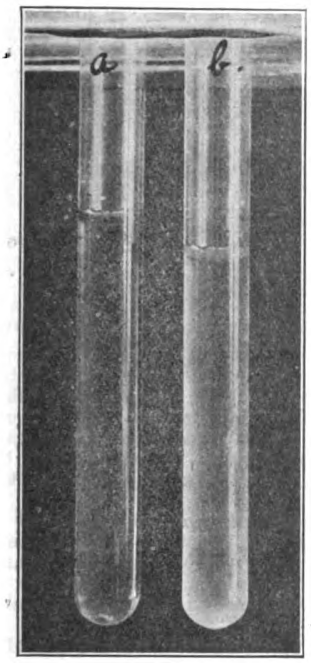
In broth, glucose broth, and peptone water at 37° C. it grows, but the fluid remains clear except for little punctate spots on the sides of the tube and a slight deposit at the bottom of the tube due to the accumulation of these "spots." The "spots" are little clumps or colonies of the organisms caused by the adhesion together of the bacteria, and corresponding with this cultural appearance chains are not found microscopically but irregular clumps.

Maltose, glucose, galactose, and dextrin are usually fermented with acid production; lactose and cane are sometimes fermented and sometimes not; while inulin, dulcite, raffinose, salicine, inosite, sorbite, and adonite are not fermented. In these latter, however, growth has taken place, as evidenced by the "spots" mentioned above, on the sides and bottom of the tubes. It is important to note that inulin is *not* fermented either alone or in His's inulin serum medium. (It is to be noted that in the preparation of these sugar media the sugars and peptone water are sterilised separately and then added to one another.) The tubes are inoculated with a pipette from a thick emulsion made by scraping blood agar growths into broth.

When the organism is grown in fluid sterile rabbit serum, the serum remains clear except for the "spots" referred to above on the sides and bottom of the tube. This differs markedly from what takes place in the case of the pneumococcus, where a dense uniform turbidity is produced through the serum. (See Fig. 1.)

The organism, therefore, differs culturally from the pneumococcus in its action on litmus milk, its fermentation of sugars, and especially its non-fermentation of inulin, and the production of punctate spots and absence of turbidity in fluid media.

---



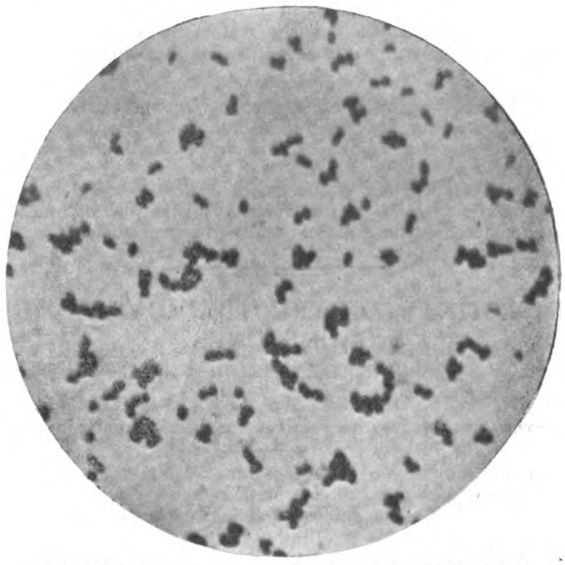
[1] "In ophthalmic practice we generally examine a smear preparation, and the difficulties which we have mentioned (i.e., of distinguishing streptococcus from pneumococcus) rarely come into the question, unless, perchance, we have to deal with a mixture of streptococcus and pneumococcus." Axenfeld: Bacteriology of the Eye, 1908. Translated by McNab, p. 188.

[2] "They (the pneumococci in the eye secretion) differ from those found in pneumonic sputum in that the capsule is not so obvious. Although many of the diplococci may be round and short, we never fail to find large numbers of the typical elongated forms from which in a Gram-stained slide a *certain diagnosis* can be given and a differentiation from other diplococci (gonococci and staphylococci) readily made." Axenfeld, loc. cit., p. 183.

Microscopical appearances of the organism in culture.—The organism is non-motile. It is a Gram-positive diplococcus, the elements of which are elongated and in a great many instances of typical lancet shape. Figs. 2 and 3 are microphotographs from 24 hour blood agar cultures of a typical pneumococcus and this organism respectively. The large number of lancet-shaped forms in Fig. 3 is especially noticeable. These photographs also show that while in the pneumococcus the diplococcal elements are usually discrete, there is a marked tendency to agglomeration with this organism. This is further shown by what happens when one filters through filter paper emulsions made from blood agar cultures of the organisms; with equally turbid emulsions the pneumococcal emulsion comes through practically as turbid as before, while the emulsion of this organism comes through practically clear. So much was this the case that comparative agglutination tests with this organism and the pneumococcus were impossible.

The size of each coccus is from 0·7 to 1μ long by 0·5μ broad at its widest part, being thus of the same size as the pneumococcus.

FIG. 1.



Photographs of cultures. Test-tube *a* contains the organisms described, grown in liquid rabbit serum. Test-tube *b* contains pneumococci grown in the same medium. Note the marked turbidity as compared with *a*.

The organism stains readily with the ordinary dyes. There are no spores present. With regard to the presence of capsules in the organism in cultures, this point has not been definitely settled. They were not obtained after several trials on fluid rabbit serum, using His's method of staining, but an undoubted culture of pneumococcus of the same age, treated at the same times and in exactly the same ways, similarly showed no capsules. (Both cultures had been subcultured on artificial media for some months.)

Inoculation experiments.—The organism has not been found to be pathogenic to either mice or rabbits. A small rabbit was inoculated intraperitoneally with some secretion, freshly removed from the eye of one of the cases, without any noticeable effect. Extensive 24-hour agar cultures immediately on isolation were injected subcutaneously into mice without effect. This is noteworthy, because during the period while this investigation was going on one of us (J. P. McG.) had occasion to be working with over 130 strains of pneumococci, and there never was a failure to produce a lethal effect on injecting subcutaneously into mice a very much smaller dose of these strains; in some cases this was also true six months after the first isolation of the strain. At this time, too, a 24-hour agar culture was applied to the conjunctival sac of a rabbit without effect.

The organism was isolated in March, 1911, and was kept going by frequent subculture on blood agar till October, when the following additional experiments were made.

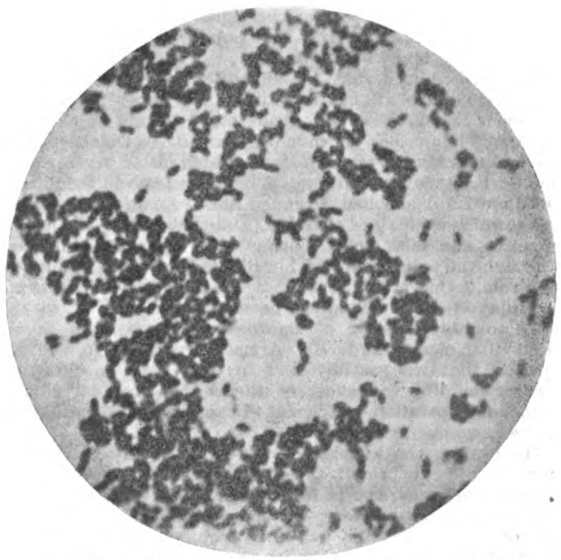


FIG. 2.

Micro-photograph of Gram-stained film from 24-hour blood agar culture of a typical pneumococcus. × 1500.

A mouse was injected subcutaneously with two 24-hour agar cultures without effect. Another mouse was inoculated intraperitoneally with two 24-hour agar cultures. It was quite well next day, but was killed for two reasons: First, to try to increase the virulence by passage, and secondly, to see if the organism would develop capsules in the tissues of an animal. Culture from the peritoneum and heart blood proved sterile, and no organisms were seen in films from the peritoneal cavity or heart blood.

FIG. 3.

Micro-photograph of Gram-stained film from 24-hour blood agar culture of the organism described. Note the agglomeration as compared with Fig. 2, and also the large number of lancet-shaped organisms. × 1500.

A small rabbit was injected intravenously with two 24-hour blood agar cultures. The rabbit remained quite

well, and frequent examination of its blood after inoculation failed to reveal the presence of any organisms. A monkey (*Macacus rhesus*) was inoculated in its left conjunctival sac with a 24-hour blood agar culture of the organism without effect.

As regards the presence of capsules in the organism *in vivo*, this point has not been settled owing to the inability to grow the organism in either of the species of animals used.

Agglutination.—As previously stated, owing to the spontaneous agglomeration of the organism, this was impracticable.

Conclusions.

1. From five cases of an epidemic of conjunctivitis in an institution we have obtained in each case a pure culture of a Gram-positive diplococcus, with elongated and lancet-shaped elements.

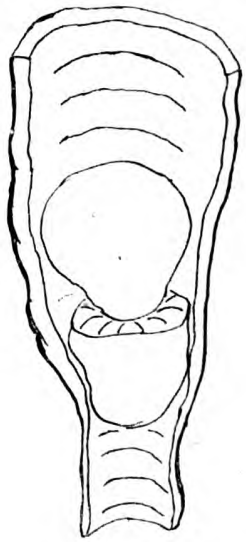
2. The superficial examination ordinarily employed in ophthalmic practice is insufficient to distinguish it from the pneumococcus, from which it really differs markedly.

INTESTINAL OBSTRUCTION CAUSED BY GALL-STONES:

A CLINICAL MEMORANDUM.

BY EDMUND OWEN, M.B. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON, W.

ON the afternoon of Saturday, June 24th last, Mr. R. Stow Armstrong asked me to see with him a lady aged about 60 years who was the subject of violent pains in the abdomen and of uncontrollable vomiting. On the day before (Friday, 23rd) she had been to see the Royal Progress, having had, before starting, some tea and toast at about 7 A.M. She had had nothing more, but on returning from the spectacle, at about mid-day, she felt very sick and, stopping the carriage, got out and vomited, bringing up, as she said, "quarts" of orange-coloured fluid. She was in great pain all that night, but she had no more vomiting till the next afternoon—at about the time of my seeing her.



I found the patient in bed, looking extremely ill, and complaining of pains which occurred in paroxysms in the right iliac fossa and round the navel. There was great tenderness in the former region, but there was none of that rigidity of the lower part of the right rectus which usually accompanies appendicitis. Her pulse, 84, was small and was dropping many beats.

The patient said that for about ten years she had been subject to sharp attacks of pain in the upper part of the abdomen, which came on about every second week, and, lasting 24 hours, left her much exhausted. In October, 1910, she had had a very severe attack, which lasted seven weeks, and during this time she had a coppery taste in the mouth. On June 22nd she had attended the Coronation procession, but towards evening of that day (Thursday, 22nd) she lost all appetite and felt sick; during the night she vomited. Through the many years of her illness her bowels had acted, as a rule, twice a day, but from the Thursday night to the Saturday afternoon there had been no action.

There was a feeling of hardness and resistance in the right iliac fossa, and Mr. Armstrong and I formed the opinion that we possibly had to deal with an intestinal obstruction due to cancer of the cæcum, and we advised immediate operation on account of rapidly increasing distress and weakness.

On opening the abdomen in the iliac fossa I came at once upon a piece of small intestine the walls of which were greatly thickened, and in the interior there was a hard mass, evidently of gall-stones. The mass was firmly wedged and the overlying intestine was discoloured, as if Nature were about to prepare the way for the escape of the mass by ulceration. By a little coaxing the stones were pushed up into the thickened and dilated piece of intestine and were easily removed through a longitudinal incision. The edges of the wound in the bowel were stitched together, and the incision was then hidden under a row of Lembert sutures of fine silk. The loop of bowel was carefully wiped with gauze and dropped back into its place, and the abdominal wound was closed. After the operation the chief trouble was caused by wind, but this gradually subsided. The pulse, which just before the operation was dropping every second or third beat, steadily improved, and in a few days it became almost regular. The surface stitches were taken out at the end of a week, the wound being soundly healed. A few days later, however, the wound had to be opened to allow the escape of a localised collection of pus, and although after this all went on well, at the end of a fortnight two sutures came away. After this the wound closed, and the patient left for the country on the twenty-fourth day, feeling, she said, better than she had done for many years.

The accompanying illustration shows in diminished scale

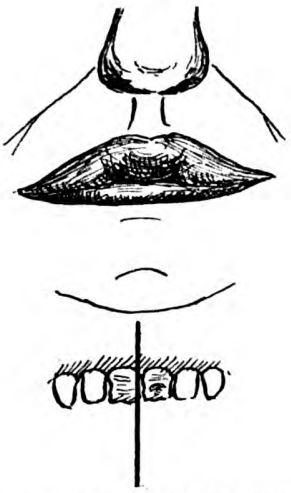
Scheme showing muscular coat of small intestine thickened in its attempt to force on gall-stones.

the two stones, and the thickening of the wall of the bowel due to the increase of the muscular tissue which had been developed in the effort to get rid of the obstruction. Doubtless the fits of intense pain were caused by the bruising of the nerves of the wall of the bowel against the stones under the powerful action of the thickened muscular coat.

The stones, which were of about the size of walnuts, were lying close together, and their ends had been so rubbed against each other by the violent muscular action that the upper part of the lower stone was smoothly hollowed out, whilst the lower end of the upper one was rounded and polished.

At first sight this case was very like one of appendicitis, showing, as it did, general distress, abdominal pains, a tender mass in the right iliac fossa, and vomiting. But there was absence of that constant sign of appendicitis—rigidity of the lower part of the rectus and of the neighbouring muscles. Still, this sign is not always present when the appendix is inflamed. Indeed, there is no sign which by itself is characteristic of appendicitis, and in certain cases pretty nearly every sign is absent. In some cases, rare, I admit, there may be advanced disease of the appendix, though the aspect of the patient, the pulse, and the temperature give no cause for alarm, and where the abdominal signs are but slightly marked. And the moral to be drawn is, that in all cases of doubt as regards the presence of appendicitis the greater safety will be in making an exploratory incision. It was quite possible that the case here related might turn out to be one of appendicitis, but it proved to be one of far greater rarity and, I think, well worthy of being recorded.

Great Cumberland-place.



NORTH-EAST LONDON POST-GRADUATE COLLEGE.—Sir James Crichton-Browne, F.R.S., will give an address on "Nerves and Nervousness," at 4.30 P.M. on Thursday, Nov. 16th, in the lecture hall of the North-East London Post-Graduate College, Prince of Wales's General Hospital, Tottenham, N., to which qualified medical practitioners are invited.

"COMFORTER" CARIES.

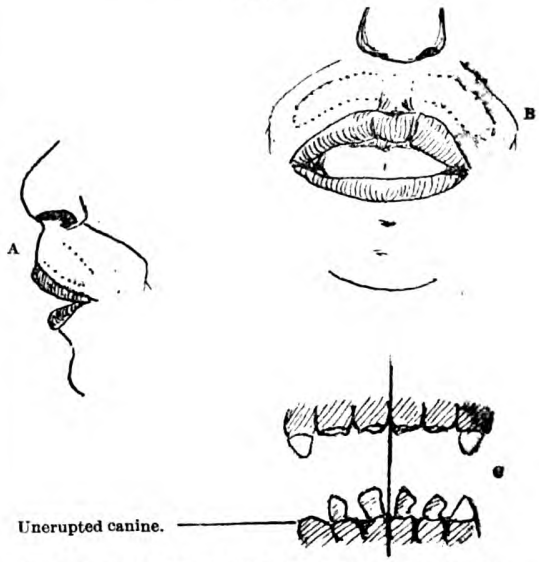
BY ERIC H. R. HARRIES, M.D., B.S. LOND., D.P.H.,
SENIOR ASSISTANT MEDICAL OFFICER, CITY HOSPITAL FOR INFECTIOUS DISEASES, FAZAKERLEY, LIVERPOOL.

CAUSE and effect seem sufficiently closely related in the conditions illustrated in this article to justify the title I have given to it. For the "nomenclature" I am indebted to the interesting contribution by Mr. W. H. Bowen on "Comforter" Otitis Media,[1] which recently appeared in these pages.

FIG. 1.

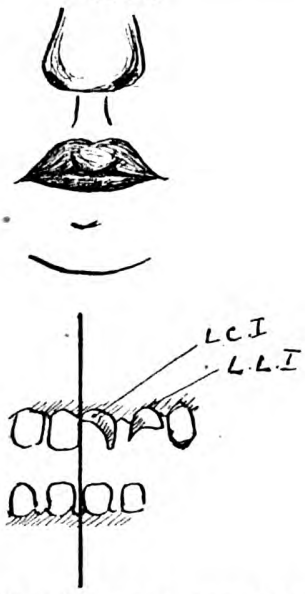
CASE 1.—A male, aged three years and seven months, admitted for diphtheria. Exhibits hypertrophy of upper lip and commencing caries of upper central incisors. Breast-fed for 13 months. No evidence of rickets or syphilis. Other teeth sound.

FIG. 2.



CASE 2.—A female, aged three years, admitted for measles. Shows some hypertrophy of upper lip. Pus at root of carious right central incisor; left central incisor has disappeared. Breast-fed for 17 months. No evidence of rickets or syphilis. Other teeth sound. R.C.I., Right central incisor.

[1] Bowen: "Comforter" Otitis Media, THE LANCET, Sept. 9th, 1911, p. 758.



The children from whom the accompanying sketches were made were admitted during the present year for various infective conditions. At the time of admission they were all sucking comforters, and a history of its habitual use was obtained from the mother in each case.

FIG. 3.

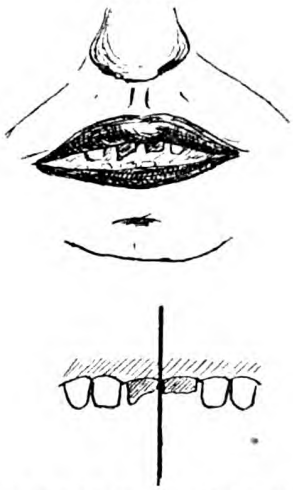
CASE 3.—A male, aged one year and five months, admitted for epidemic diarrhœa, using comforter. The mother stated that the child had "a new one nearly every day as he bites them up." The case exhibits deformity of upper lip and a well-marked visible and palpable hypertrophied segment of the orbicularis oris. The upper incisors are represented by carious stumps; the lower incisors are badly formed, small, and irregular. Palate somewhat highly arched. Adenoids not marked. Never breast fed. "Sterilised" milk and lime water for 13 months. A, Profile; hypertrophied segment of orbicularis oris shown by dotted lines. B, Hypertrophied segment of orbicularis oris shown by dotted lines. Appearance of child's mouth in repose. C, Upper incisors decayed almost to alveolar margin. Lower incisors small and irregular.

FIG. 4.

CASE 4.—A female, aged three years, admitted for measles. Constantly sucked "dummy." Shows caries of left central and lateral incisors. Other teeth sound. No evidence of rickets or syphilis. Breast-fed for 17 months. L.C.I., Left central incisor. L.L.I., Left lateral incisor.

Most small children of the poorer classes in Liverpool, as elsewhere, suck comforters, and the sketches of course only represent a few cases under my personal observation in

which I have noted extensive caries, or marked hypertrophy of the upper lip, or both, associated with persistent "indulgence" in the "dummy." It would be as foolish to assert that caries results in all or the majority of infants who have been indulged in the comforter for lengthy periods as to assert that all smokers of clay pipes develop epithelioma. I present these cases merely as concrete instances of the damage which, I submit, has been caused by the appliance.



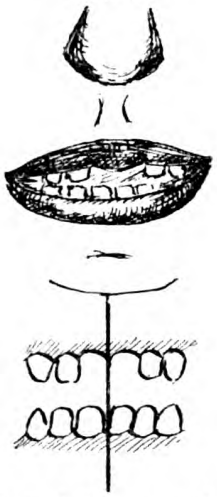
The details of each case are noted under the corresponding figure:—

Case 1 shows marked hypertrophy of the upper lip and commencing caries of the upper central incisors. Case 2 also exhibits some hypertrophy and asymmetry of the upper lip. The left upper central incisor has disappeared, while the right upper central incisor shows advanced caries and pus at the alveolar margin. Cases 1 and 2 were breast-fed for 13 and 17 months respectively.

Case 3 shows a different form of hypertrophy—viz., that of a segment of the orbicularis oris. I allowed the child to suck its comforter in order to observe what happened. I was left in no doubt that this hypertrophied segment of muscle had been produced by constant sucking and—if I may use the term—"prehensile" efforts to keep the "comforter" in position. The parents both had excellent teeth and were surprised at the way the child's teeth had decayed. The extensive nature of the caries is shown in the diagram. The child was 17 months old at the time of observation, and had never been breast-fed. Further details are given under the figure.

In Case 4 the child exhibited marked caries of the two upper left incisors. She had been breast-fed for 17 months. Case 5 shows caries of the two upper central incisors. The child's palate was also highly arched, and it had marked adenoids.

FIG. 5.



CASE 5.—A male, aged three years and five months, admitted for scarlet fever. Shows caries of upper central incisors. Persistent "dummy" user. The mother said the child sucked the "dummy" all night. High-arched palate. Marked adenoids. No evidence of rickets or syphilis. All other teeth sound.

Case 6 was admitted with a comforter, as were all the others. The two upper central incisors were missing, and the gap was completely filled by the dummy. The teeth, however, had been knocked out as a result of a fall. The case is, therefore, not a genuine one, but I have included it as an interesting coincidence.

It will be noted that with one exception all these children were round about three years of age. The mothers had never taken sufficient trouble to break the child of its habit of sucking the "accursed instrument," as Dr. Eric Pritchard calls it. That the "comforter" is quite unnecessary is shown by the readiness with which infants in hospital—hitherto persistent "devotees"—dispense with its use. The class of children from which the present cases were drawn possess mothers with no powers of observation at all, and with imaginations equal to any emergency, hence I am unable to give any reliable dates of onset of the caries. I have eliminated rickets and syphilis in each case. Except for the acute condition for which the children were admitted they appeared to be constitutionally sound. Only the teeth indicated were affected. Dentition in Case 3 was not complete, the child being only 17 months old. In the remaining cases primary dentition was complete.

FIG. 6.

CASE 6.—A female, aged three years and seven months, admitted for scarlet fever. Sucking "dummy" on admission which exactly fitted the gap. Constantly uses "dummy." The case is, however, spurious, as the teeth were knocked out by a fall.

If there be some other factor of a general nature causing this early caries it is curious that no other teeth were affected. Whether the condition is produced by some direct action of the rubber upon the teeth, or whether it is due to the introduction of septic matter which is scraped off by and worked around the upper incisors, I am unable to say. Possibly both factors are at work. The hypertrophy and asymmetry of the upper lip noted in these cases can readily be understood.

The question of dental caries in children is much to the front just now.[2] This small contribution to the subject may, therefore, be of some interest. These cases do not represent all in which I have come across the condition, but some of the most marked examples only.

Liverpool.

THE BLOOD CHANGES IN BILHARZIASIS,*

WITH SPECIAL REFERENCE TO EGYPTIAN ANÆMIA.

BY H. B. DAY, M.D., B.S. LOND., M.R.C.P. LOND.,

PROFESSOR OF CLINICAL MEDICINE, EGYPTIAN GOVERNMENT SCHOOL OF MEDICINE; PHYSICIAN, KASR EL AINY HOSPITAL, CAIRO.

THE recent article in THE LANCET by Captain G. W. G. Hughes, R.A.M.C.,[1] draws attention to the extent of the ravages of bilharziasis and ankylostomiasis in Egypt, more particularly in the perennially irrigated area of the Delta. Although the native agricultural population are the main sufferers Europeans may also be attacked as in a case of bilharziasis recently described in these columns by Mr. F. C. Madden.[2]

Bilharziasis is generally contracted in childhood, almost certainly by bathing in infected water. Thus Kautsky[3] found 78 per cent. of school children infected, while among adult males at least 35 per cent. have the disease (F. Milton). Sandwith[4] states that it is found in 38 per cent. of necropsies. The symptoms may last as long as 15 or 20 years after infection, but the severe cases commonly seen in male adults working in irrigated fields are due to continued reinfection.

Of late years the blood changes in bilharziasis, first noted

[2] Vide Wheatley, "The Causes of Dental Caries," Public Health, September, 1911.

* With the advice of Professor Looss I have in the word "bilharziasis" adopted the new spelling (bilharziasis, not bilharziosis) in conformity with the nomenclature of other infections such as ankylostomiasis and trypanosomiasis. The superior figures refer to the bibliography at the end.

by Coles, have been studied by several workers. In 1903 Douglas and Hardy[5] published an analysis of 50 cases occurring in British soldiers infected in South Africa, dealing principally with the qualitative changes in the leucocytes. Their results were confirmed by Balfour[6] of Khartoum, and also by Kautsky[3] and lately Zweifel[7] of Cairo, who both call special attention to the anæmia produced by loss of blood in this disease, which they hold to be the main cause of the anæmia so prevalent in Egypt.

The purpose of this paper is to show that while certain changes in the leucocytes and moderate anæmia are characteristic of bilharziasis, severe anæmia is rare except in cases complicated by sepsis or other disease. Further analysis of a series of cases of severe anæmia admitted to hospital shows that ankylostomiasis is the common, though not the exclusive, cause of the so-called Egyptian chlorosis.

In a patient suffering from bilharziasis we may distinguish at least four distinct factors which influence the blood changes: (1) The presence of the bilharzia worms in the blood-vessels; (2) the loss of blood accompanying the discharge of ova; (3) septic infection of ova-discharging surfaces, which in the case of the intestine may lead to exhausting diarrhœa—"bilharzial dysentery"; and (4) the coexistence of other diseases, of which the most common are ankylostomiasis, endemic cirrhosis, and pellagra.

1. The presence of bilharzia worms in the blood-vessels causes characteristic alterations in the white corpuscles. There is generally a slight leucocytosis with a marked increase in the numbers of eosinophile and large mononuclear cells. The polynuclear leucocytes are diminished, while lymphocytes are unaffected. The following figures are taken from various writers:—

Author.	No. of cases examined.	Average total number leucocytes.	Percentage.				Total eosinophiles per c.mm.
			Polynuclear.	Lymphocytes.	Mononuclears.	Eosinophiles.	
Douglas and Hardy	50	Increased.	44·6	25·7	12·5	16·5	—
Kautsky	22	10,000	43·0	40·0		17·0	1700
Zweifel	16	9,737	66·0	29·5		14·4	1401
Self	15	9,476	45·3	21·4	9·5	23·7	2246

The figures of Douglas and Hardy and of Kautsky are almost identical and represent the average uncomplicated case. Zweifel's figures are taken from adult patients attending hospital for treatment, some of whom had septic complications. Hence the much higher polynuclear average and the lower eosinophilia. My own figures are taken from an examination of 15 cases of uncomplicated bilharziasis admitted to hospital, the details of which are given in the table (Series 1.). Such in-patients represent mostly severe cases, hence the higher eosinophilia. The average number of large mononuclears was not so large as in the series published by Douglas and Hardy, but their figures were raised by the inclusion of cases with old malarial infection.

The eosinophilia appears due to the products of metabolism of the bilharzia worm which are excreted directly into the blood of the host. It can be artificially produced by the injection of dead worms or hatched ova (the ciliated miracidia). The following table shows the result of the subcutaneous injection of eight young worms (sterilised by heat) in a healthy adult:—

—	Before injection.	After six hours.	Second day.	Third day.	Fourth day.	Sixth day.	Eighth day.
Total No. of leucocytes ...	4800	5000	4986	5817	6233	4155	4986
Percentage: Polynuclear	70·0	75·5	75·0	77·0	60·5	56·6	68·3
Percentage: Lymphocytes	22·5	20·0	23·0	18·0	30·5	32·0	21·3
Percentage: Large mononuclears	4·0	2·5	1·0	3·0	3·0	5·6	4·0
Percentage: Eosinophiles	3·5	2·0	1·0	2·0	6·0	6·0	3·3
Total eosinophiles (per c.mm.)	148	100	50	116	374	249	164

A similar result followed the injection of 1000 miracidia:—

—	Before injection.	Second day.	Third day.	Fourth day.	Fifth day.	Seventh day.	Ninth day.
Total No. of leucocytes ...	4571	4255	6233	5403	5403	4986	5403
Percentage: Polynuclear	76·0	66·0	61·5	70·0	65·6	60·0	72·0
Percentage: Lymphocytes	15·75	28·75	31·75	23·3	28·6	32·0	20·0
Percentage: Large mononuclear	3·5	2·5	4·25	3·3	2·6	1·25	5·0
Percentage: Eosinophiles	2·25	3·75	2·5	3·3	3·0	6·75	3·0
Total eosinophiles (per c.mm.)	103	159	156	178	162	336	162

It will be seen that the chief changes are a slight general leucocytosis due to an increase of eosinophiles and lymphocytes, the other varieties being hardly affected. Examination of the injected area showed a dense infiltration with eosinophiles. Such local accumulation explains the presence in bilharzial urine of eosinophiles in much higher proportions than in the blood. Conversely, when the disease is of limited extent the removal of bilharzial tissue containing worms will lower the eosinophilia. Thus in the example given (Case A) a boy with extensive disease of the penis and perineum had the para-urethral infiltration excised with a marked effect on the blood within a week.

As far as can be judged from clinical examination the degree of eosinophilia and other blood changes are roughly proportional to the intensity of the affection, provided the patient's general condition be good. The highest eosinophilia was obtained in the case showing the most extensive lesion, while in old-standing cases with only a few calcified ova in the urine there may be none, as the worms have probably died out.

2. The constant loss of blood due to the discharge of ova through a mucous membrane causes a secondary anæmia proportional to the duration and severity of the hæmorrhage. The loss of blood varies greatly, even in the same patient, but in the large majority of cases only a few drops are noticed at the end of micturition or defæcation. Bilharzial disease of the intestine is especially apt to cause anæmia on account of the tendency to septic infection and diarrhœa.

The vegetable diet of the Egyptian predisposes him to anæmia, and the average hæmoglobin percentage is under 90 in health. In his examination of school children Kautsky found an average hæmoglobin percentage of from 80 to 90 in health, while in those infected with bilharziasis it was reduced to 75. The number of red cells was little reduced (average 4,860,000), but even in cases with 5,000,000 or more red corpuscles the hæmoglobin was reduced. These figures are of special value as complications were rare, and ankylostomiasis specially excluded. In my series of nine uncomplicated cases the average count was 4,112,000, but these represent mostly severe cases and not the average condition. The anæmia is distinctly of the chlorotic type, with a low colour index; nucleated red cells are only occasionally found.

In contrast with the anæmia produced by ankylostomiasis that due to bilharziasis is much more amenable to treatment with simple hæmatinics. Thus a boy of 15 (Case B) with intestinal bilharziasis, anæmic for three years, had on admission only 20 per cent. hæmoglobin, but on iron and arsenic this increased to 60 per cent. in a fortnight. In spite, however, of continued treatment no further improvement was obtained. Such anæmia greatly obscures the leucocytic changes characteristic of the disease. The reappearance of the typical blood-picture with improvement of the anæmia under treatment is well shown in the Cases B and C. No doubt if the blood examination in Series 1 had been made at the end instead of at the beginning of treatment the average eosinophilia would be greater.

3. In many cases of severe bilharziasis—due to continual reinfection—septic complications ensue with disastrous results. These form the great majority of those cases admitted to hospital. There are three main channels of sepsis. In bilharzial infiltration of the para-urethral and perineal tissues septic infection is apt to spread from the urethra, rectum, or skin, leading to fistulous openings and chronic suppuration. This is the least dangerous form, and

free excision may effect a cure. Advanced bilharzial disease of the bladder is often complicated by sepsis, which may readily prove fatal by involvement of the kidneys. This extension occurs the more readily since the ureters are often partially blocked below by bilharzial growth and dilated above. Intestinal bilharziasis is generally associated with some degree of sepsis, and when the disease is extensive considerable ulceration may ensue from detachment or destruction of papillomata Not only bacteria but amœbæ and flagellates flourish, setting up a chronic dysentery which is most refractory to treatment.

A series of 20 cases of bilharziasis complicated by septic infection, usually of long standing, is detailed (Series 2), which on comparison with the figures of aseptic cases reveals the following differences: (*a*) The average age is greater, corresponding to the longer duration of the disease. (*b*) The leucocytosis is higher from an increase in the polynuclears, but the eosinophilia is much reduced The lymphocytes and large mononuclear cells are unaffected. (*c*) The anæmia is much more pronounced, as shown by the average number of red corpuscles (3,354,000). The hæmoglobin is reduced to a still greater degree, and I have notes of five other cases (to be referred to later) in which the average percentage was only 18·5.

4. The association of other diseases with bilharziasis similarly tends to increase the anæmia and obscure the characteristic leucocytic changes. Amongst the fellaheen the commonest general diseases after bilharziasis are ankylostomiasis, endemic cirrhosis, and pellagra In each of these three last affections at least as much anæmia may be present as in a case of uncomplicated bilharziasis. Reference to the ten cases detailed in Series 3 will show that the average loss of red corpuscles exceeded that found in septic bilharzia cases.

Endemic cirrhosis affects a considerable proportion of the poorer population, quite 10 per cent. It is closely allied to, if not identical with, Banti's disease and causes anæmia of a splenic type with leucopenia and relative lymphocytosis.[8] Associated with bilharziasis it lowers the eosinophilia and aggravates the anæmia, which is much more difficult to ameliorate by treatment. Pellagra acts in much the same way.

It will be seen that the average eosinophilia in the four cases of combined ankylostoma and bilharzia infection was under 11 per cent., whereas in cases of aseptic simple bilharziasis it was considerably higher (23·7). Although ankylostomiasis causes a high eosinophilia in the early weeks after infection, this is soon reduced, especially when anæmia is established (Boycott)[9].

In estimating the relative action of bilharziasis and ankylostomiasis in causing the well-known Egyptian anæmia, both Kautsky and Zweifel hold that the former alone is the main factor. They base their conclusions on the following statistics:—

Author.	Condition.	Numbers examined.	Average Hb.	Minimum.
Kautsky.	Uninfected children.	22	80–90	65
,,	Bilharzia alone.	71	70–75	50
Zweifel.	,, ,,	16	70	55
Kautsky.	Bilharzia and ankylostoma	26	70–75	45
Zweifel.	,, ,,	5	70	60
Kautsky.	Ankylostoma alone.	5	80–90	75

Zweifel summarises his results thus: 1. Bilharzia ova are more commonly found than ankylostoma. 2 Greater visible loss of blood occurs in bilharziasis. 3 There is no difference in loss of hæmoglobin between cases infected with bilharzia and those infected with ankylostoma as well. 4. The hæmoglobin percentage of the blood of normal people and of those infected with ankylostoma is the same. 5. The blood of bilharzia patients has a lower hæmoglobin value than the blood of healthy persons or of those infected with ankylostoma. No worker in Egypt will dispute the first two conclusions, but the insignificant rôle assigned to ankylostomiasis appears to me unjustified. Kautsky himself is careful to state that he selected children in preference to adults for his investigations on account of the lower incidence of septic complications and of ankylostomiasis in the former. Further, although the fæces of 25 per cent. of the children examined contained ankylostoma ova, these were only found in scanty numbers; five or six slides were frequently searched before finding one.

It is obvious, as Boycott well puts it, that we must distinguish between cases of ankylostoma infection and patients ill with ankylostomiasis. The terrible anæmia that can be produced by this disease is well exemplified by the experience at Porto Rico, where half the agricultural population had less than 50 per cent. hæmoglobin. The statistics of Kasr el Ainy—the largest hospital in Egypt—show that during the last year 450 cases of ankylostomiasis and 285 cases of bilharziasis were admitted. 68 per cent. of the bilharzia patients were taken in for surgical treatment and showed moderate or slight anæmia, while of the remaining 32 per cent. in the medical wards only a small proportion showed marked anæmia (under 50 per cent. hæmoglobin). The average Egyptian fellah makes no complaint of a diminution of hæmoglobin to 75 per cent., and our experience shows that it is most exceptional for any patient to seek admittance for simple anæmia until his hæmoglobin is reduced far below this figure. Thus Sandwith found that the average amount of hæmoglobin in 173 ankylostoma cases examined on admission was only 26 per cent. In only three patients did the red corpuscles number over 4,000,000, while in 28·3 per cent. they were reduced below 2,000,000.

In order to determine the relative effects of various diseases in producing anæmia in Egypt I have analysed a series of 90 cases of severe anæmia admitted to my wards. The average hæmoglobin percentage was below 20 (highest 40; lowest five); the observations were made by Oliver's hæmoglobinometer and his daylight reading scales. It must be remembered that this intense anæmia is generally more apparent than real, since the volume of blood in the body may be largely increased, as shown by Haldane's CO method.

Analysis of 90 Cases of Severe Anæmia.

Main infection.	Complication.	No. of cases.	Average Hb.
Ankylostomiasis.	(None evident.)	52	17·92
	Endemic cirrhosis.	14	15·07
	Pellagra.	5	16·00
	Pellagra and cirrhosis.	1	22·00
Bilharziasis.	Sepsis.	5	18·50
	Cirrhosis.	1	20·00
Ankylostomiasis with bilharziasis.	—	8	14·50
	Cirrhosis.	1	18·00
	Pellagra.	2	15·00
Gastric carcinoma.	—	1	35·00

It will be noted that ankylostomiasis alone or in combination with other diseases was present in all but seven cases, and that the lowest hæmoglobin values were obtained in cases of combined infections. Bilharziasis with its sequelæ was alone responsible for just over 5 per cent., but had an important share in another 13 per cent. It may be objected that in only 18 per cent. of the cases was bilharziasis held to be an important factor or the sole cause of the anæmia, whereas a much larger proportion of hospital patients have the disease. It is quite true that microscopical examinations demonstrate the presence of ova in a larger percentage, but I do not believe such slight infections to be responsible for such high degrees of anæmia for the following reasons:—(*a*) In none of the cases excluded was there albumin or pus in the urine, nor diarrhœa or blood in the stools. (*b*) Unless septic complications such as cystitis and diarrhœa were present a slight bilharzial infection did not cause marked anæmia. (*c*) Improvement in the anæmia, ascertained by regular hæmoglobin estimations, was entirely dependent on the expulsion of ankylostoma worms.

To summarise the results of these investigations:—

1. Bilharziasis is characterised by a slight general leucocytosis due to a considerable increase in eosinophile and large mononuclear cells, the polynuclears being diminished.

2. These changes are roughly proportional to the intensity of the disease provided the patient's general condition is good. The presence of grave anæmia, sepsis, or complicating disease obscures these changes, which reappear on improvement.

3. Secondary anæmia is present to a moderate degree in

* Both very anæmic. No. 8 on admission had only 16 per cent. hæmoglobin.

most cases. Even when the red corpuscles show no reduction in numbers there is a loss of hæmoglobin (Kautsky).

4. Profound anæmia may be caused by excessive loss of blood, prolonged suppuration, and especially chronic diarrhœa.

5. Bilharziasis is the commonest worm infection in Egypt and is responsible for most cases of moderate anæmia in children.

6. Ankylostomiasis incapacitates a larger proportion of the population than does bilharziasis.

7. Ankylostomiasis is a much more frequent cause of severe anæmia than is bilharziasis. The term "Egyptian chlorosis," if used at all, should not be applied to the secondary anæmia produced by bilharziasis.

8. The combination of both infections or the association with other diseases, such as cirrhosis, tends to aggravate the anæmia.

In conclusion, I wish to thank my colleagues at Kasr el Ainy Hospital for details supplied and permission to examine patients under their care.

THE

COMPARATIVE VALUE OF THE VARIOUS METHODS OF ANTISYPHILITIC TREATMENT AS ESTIMATED BY THE WASSERMANN REACTION.

BY H. WANSEY BAYLY, M.R.C.S. ENG., L.R.C.P. LOND.,
PATHOLOGIST TO THE LONDON LOCK HOSPITALS.

(*From the Bacteriological Department, St. George's Hospital.*)

IN THE LANCET of May 7th, 1910, I published, in conjunction with Mr. Charles Gibbs, a preliminary note on this subject and recorded the results obtained in 231 cases in which a qualitative Wassermann reaction was used, and 93 cases in which the test was made roughly quantitative by the use of two amounts of complement. Since that date I have made 270 additional quantitative estimations of the Wassermann reaction in 100 cases. The advent of salvarsan has delayed the publication of this completed note as I thought it best to wait till I had had nine months' experience of the new remedy.

The technique used in the estimation of the Wassermann reaction has been the original one, with the exception that for antigen rabbit heart extract has been used instead of extract of syphilitic organs. I have made numerous parallel experiments with rabbit heart extract and the extract of syphilitic organs prepared by Professor Wassermann and sent out from his own laboratories, and have obtained quite as, if not more, satisfactory results with the rabbit heart extract as with the syphilitic organs extract.

I am still of the opinion that the original technique (with the above modification) is far preferable to the numerous simplified methods (Stern, Fleming, &c.) in which constants are replaced by variants.

My further experience confirms our original conclusions that inunction and intramuscular injection are by far the most rapid methods of producing a negative Wassermann reaction by mercurial treatment.

Salvarsan usually produces a negative reaction more quickly than mercury, but apparently the percentage of negative results after one or two intravenous injections of the doses employed (0·4 grm.) is lower than that observed after a year's course of efficient mercurial treatment.

The following tables give the results that were obtained with the various treatments as far as the Wassermann reaction is concerned. + signifies complete inhibition of hæmolysis, ± partial inhibition, and − complete hæmolysis. Complete inhibition of hæmolysis with both amounts of complement I call "strongly positive," while "positive" denotes that though there is complete inhibition with the smaller amount of complement there is hæmolysis with the larger amount. If the hæmolysis with the smaller amount of complement is partial only, I record the result as "doubtful." All the cases recorded were "strongly positive" before the treatment was commenced, and therefore "positive," "doubtful," and "negative" all show influence of treatment in a roughly quantitative manner.

Percentage of cases	10		10		10		70	

¶ Very frequently cases are met with that begin at "strongly positive," pass through the "positive" and "doubtful" stages and end at "negative." Of the total 53 cases treated with salvarsan and examined four weeks and over after treatment 30 (57 per cent.) became negative, while of 50 cases examined under four weeks only 9 (18 per cent.) were negative.

The results obtained, which give 42 per cent. negative after intramuscular injections, 52 per cent. after one intravenous injection, and 70 per cent. after two intravenous injections, seem to indicate that the intravenous route is the best, and that at least two injections should be given.

The dose given in the great majority of intravenous cases was 0·4 grm., and now that we know that usually larger doses can safely be given, we may hope to obtain a higher percentage of negative results and a lower percentage of relapses.

It will be seen from Table III. that 70 per cent. of cases treated with salvarsan became negative in from four to eight weeks after the second intravenous injection, and that 70 per cent. of these negatives remained negative six to nine months afterwards. Just about 50 per cent., therefore, of cases that before treatment were strongly positive became negative, and still remained so when examined six to nine months after treatment. Of course, a negative reaction persisting for six or nine months does not necessarily mean permanent cure, but it is at least extremely encouraging that there is no pathological evidence of relapse in half the cases. In some cases salvarsan, even in repeated doses (sometimes as many as six have been given), has no effect whatever on the reaction. I am inclined to think that cases that are going to relapse will show evidence of such relapse by the Wassermann reaction in under six months in the great majority of instances. On comparing Tables I., II., and III. it will be seen that only 48 per cent. of cases treated with pills become negative after 18 months' treatment, whereas 80 per cent. become negative after three courses (one year's treatment) of intramuscular injection. How many of these, however, would remain negative six months later if all treatment were discontinued it is impossible for me to say, as I have not had opportunities for such investigation. At the London Lock Hospitals we have considerable difficulty in getting patients to return for blood examinations after they have severed their connexion with the hospital.

I have had but little opportunity of investigating the effect on the reaction of treatment by inunction or suppositories, but the short series examined have been recorded in Tables IV.

TABLE IV.—*Suppositories (33 Cases).*

Treatment for Six Months and Under.

Complement	5%	15%	...	5%	15%	...	5%	15%	...	5%	15%
Wassermann reaction	+	+	...	+	−	...	±	−	...	−	−
Number of cases ...	20		...	6		...	4		...	3	
Percentage of cases ...	61		...	18		...	12		...	9	

TABLE V.—*Inunction (26 Cases).*

Treatment of Two to Three Months.

Complement	5%	15%	...	5%	15%	...	5%	15%	...	5%	15%
Wassermann reaction	+	+	...	+	−	...	±	−	...	−	−
Number of cases ...	3		...	10		...	3		...	10	
Percentage of cases ...	11½		...	38½		...	11½		...	38½	

and V. It would appear that suppositories are but little if at all superior to pills and that inunction is a very efficacious method of mercurial administration. I regret that I am not able to record and compare parallel tables of results following treatment by inunction and intramuscular injections.

If rapidity of change of reaction be taken as a test of efficiency of treatment I should place salvarsan first, inunction or intramuscular injection of insoluble mercurial compounds second, and mercurial pills and suppositories a bad third. I consider that the results obtained suggest the advisability of combined salvarsan and mercurial treatment.

The majority of the cases were female patients at the Lock Hospital under the care of Mr. Arthur Shillitoe and Mr. Charles Gibbs. The work has been carried out at St. George's Hospital by the kind permission of Dr. Charles Slater, director of the clinical laboratories.

Upper Berkeley-street, W.

ROYAL SOCIETY OF ARTS.—The Royal Society of Arts begins its 158th session on Wednesday next, Nov. 15th, with an address from Lord Sanderson, G.C.B., the chairman of the council. Five meetings are announced before Christmas, at which papers will be read on the Industrial Progress of America, by Professor James Douglas, LL.D.; on the Efficiency of the Aeroplane, by Mr. A. E. Berriman; on British Guiana, by Mr. J. A. J. de Villiers; on London Transport, by Mr. W. Yorath Lewis; and on Bengal Fisheries, by Dr. J. Travers Jenkins. Four Cantor lectures on "The Carbonisation of Coal" will be delivered by Professor Vivian Lewes, and two juvenile lectures on "Soap Bubbles" will be given in January by Mr. C. V. Boys, F.R.S. A long list of papers for the meetings to be held after Christmas is also published.

REMARKS ON THE MODERN METHODS OF DIAGNOSIS

AS ILLUSTRATED BY A CASE OF TUMOUR OF THE LUNG.

BY NORMAN DALTON, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO KING'S COLLEGE HOSPITAL.

THE patient, a man aged 51, was sent into King's College Hospital by Mr. T. A. Clarke of Wandsworth Common on April 7th, 1911, and placed under my care.

The family and past history were unimportant. On Jan. 9th, 1911, the patient felt a stabbing pain just below the right nipple. In the light of subsequent events it is probable that this pain occurred when the growth in the lung first reached the pleura. It was not made worse by coughing or deep breathing. He coughed a good deal and brought up ordinary phlegm. On the 10th he went to Mr. Clarke's surgery, who found pleurisy on the right side, but no signs of fluid. The patient attended at the surgery nearly every other day until Feb. 12th, when he felt better and went back to work, but in five days he was obliged to give up work on account of the pain below the right nipple. Since January he had steadily lost flesh and strength. On Feb. 17th he was seen at home, and frictions were found round the right nipple. He was under observation during the rest of February and March. During this time the temperature showed slight remittent fever, not exceeding 100° F.; the loss of flesh and strength continued, and the friction was still heard, but his chief complaint was a feeling of indigestion, probably caused by growths in the mediastinum. Towards the end of March the temperature became higher, often reaching 102°; he had night sweats, and the sputum contained plugs of pus with some blood. No tubercle bacilli were found. There was also now some dyspnœa, and crepitations were heard at the right base behind, and round the right nipple.

On admission the man looked very anxious, was hectic and breathed very rapidly. The pulse was 120, the breathing 28, and the temperature 102·4°; and I may say here that during the eight weeks in which he was in the hospital the pulse varied from 140 to 112, and the breathing from 40 to 28, while the temperature was remittent and varied from 103·8° to 99°, reaching the normal on only a few mornings. During the last week of his life the rises were less, but the temperature was never subnormal for 24 hours. There were no rigors at any time.

To return to the physical examination of the patient, we found that the apex beat of the heart was displaced to the left, being half an inch outside the left nipple, but it was not higher than normal, as is often the case in subphrenic abscess. The heart was otherwise normal, as was also the left lung. On the right side there was dulness from the upper limit of normal liver dulness to the right nipple, extending laterally from the sternum to about one inch outside the nipple. Over this area the breath sounds, vocal resonance, and vocal fremitus were lost. Around this area in front, in the lower axilla, and all over the right base there were slight crepitations, but no definite dulness nor any other abnormality. The upper part of the right lung was quite normal.

There was a fair amount of sputum, the character of which never changed. It was very thick, though not so tenacious as that of croupous pneumonia. It was uniform in consistence and colour, the latter being a reddish opaque brown, not at all translucent or currant-jelly-like. It was rather like the contents of a tropical abscess of the liver, so much so, that my house physician, Mr. T. H. Whittington, had it examined for amœbæ, but with a negative result. It was not to the naked eye like a mixture of pus and blood, but microscopically it contained red corpuscles and what looked like white blood corpuscles intimately mixed, and streptococci. The round white cells were very necrotic, and one of the most remarkable things about the tumour when examined after death was the rapid necrosis of the sarcomatous cells (see further on). There was nothing abnormal about the abdomen. The urine was normal.

The physical signs and high remittent fever suggested an empyema, and this idea was strengthened by finding a leucocytosis of 38·800 per c.mm., and a well-marked relative

increase of polynuclear corpuscles. The presence of blood in the sputum suggested an infarction as the cause of the empyema, more especially as the illness began with a sudden stabbing pain, but there was nothing in the rest of the body which might be the source of an embolus. The empyema might have followed a small aspiration pneumonia or possibly a subphrenic abscess. The position of the dulness was rather in favour of the last hypothesis. A needle was inserted about 1 in. below the right nipple, but no pus was found. Shortly after this the patient was X rayed. A shadow was seen corresponding to the area of dulness which we had found, so we did not get much help with respect to the nature of the dulness, but, on the other hand, it was seen that the diaphragm was moving freely on the right side, which made subphrenic abscess unlikely.

At this point we would have been content with a diagnosis of tumour of the lung but for the high fever and the high leucocyte count. In the early morning of April 24th the patient had a great increase of the pain about the lower part of the sternum and became rather collapsed, the temperature falling to 98°. During the day he passed six loose stools (he had had no diarrhœa before), the last five of which contained pus and blood. This revived the idea that an abscess was present in some position from which it could burst into the bowel. There was, however, no change in the physical signs nor in the condition of the patient. He soon rallied from the shock, no change in the physical signs followed, and in two days' time the patient was neither better nor appreciably worse than he had been before the pus appeared in the stools.

I was thus led to think that the blood and pus were not due to the rupture of an abscess into the bowel, but to a terminal colitis with ulceration of some solitary glands. At my request, therefore, Dr. P. B. Ridge tried the agglutination reaction of the patient's blood with Flexner's and Shiga's bacilli. No agglutination of the former occurred, but the serum in dilutions of 1 in 10 and 1 in 30 agglutinated Shiga's bacilli, though slowly. This, Dr. Ridge informed me, was a definite though weak reaction. The agglutination of Shiga's bacilli by blood serum is not a reliable sign of ulcerative colitis or dysentery, for it may occur in cases of multiple papillomata of the colon which end in cancer. It presumably means that Shiga's bacilli are infecting the blood, probably through some disease of the colon, but it does not indicate what the lesion in the colon is.

In this connexion I would like to mention the case of a child, now under my care, who is recovering from an attack of prolonged remittent fever. The temperature chart did not resemble that of enteric fever, nor were any symptoms of that disease present, but the child's blood agglutinated both typhoid bacilli and the bacilli of Shiga. If this child really had enteric fever, I would explain the agglutination of Shiga's bacilli by suggesting that it was one of those rare cases of typhoid in which follicular ulcerations occur in the colon, such a lesion being, in my opinion, sufficient to cause the blood to agglutinate Shiga's bacilli.

But to return to the case of tumour of the lung. The pus and blood soon disappeared from the stools, so that if a colitis had occurred it was certainly not a terminal one. By May 15th the dulness, loss of breath sounds, &c., had extended to about an inch above the right nipple, and an X ray examination showed a shadow corresponding to the dull area, and it could now be seen that the right side of the diaphragm no longer moved with respiration. The last point of interest in the case is that about a week before his death on June 1st a subcutaneous tumour of about the size of a white bean was found below the right nipple, exactly at the spot where the puncture had been made when the dull area was explored on the patient's admission to the hospital. It was freely moveable under the skin and over the chest wall, so that it was not in continuity with the tumour inside the chest.

Necropsy.—At the post-mortem examination a large tumour was found in the front part of the lower lobe of the right lung. It pushed down the liver in front and it touched the chest wall over the area which was found to be dull during life. The subcutaneous tumour mentioned above was proved to be not in continuity with the main tumour in the lung. There were some growths in the mediastinum. The tumour seemed to have been originally white and very soft, but everywhere, even in the small subcutaneous nodule, which was probably not more than a fortnight old, it had broken down to the diffluent reddish-brown material which had constituted the sputum. There were no secondary deposits in other viscera.

Microscopically the growth was found to be a round-celled sarcoma, but the degeneration made microscopy difficult. We had some idea at the post-mortem examination that the primary growth may have been in the thymus, as in the position of that organ there was a diffluent mass of growth even more degenerated than the others, and, therefore, probably of greater age. But, under the microscope, no evidence in support of this view could be obtained, and in the few cases of mediastinal growth which I have seen and have believed to have originated in the thymus, the tumours have not been specially hæmorrhagic nor prone to degeneration.

The "lung" around the tumour was intensely inflamed, the air vesicles being filled, some with leucocytes and a few epithelioid cells, and some with fibrin, as in a croupous pneumonia. A careful examination of the whole alimentary canal and its surroundings was made, but no trace of a perforation or an ulcer could be found, nor any sign that an abscess in contact with the alimentary canal had existed.

Remarks.—The points of interest in this case are, first, the apparent acute onset and the rapid growth of the tumour; secondly, the high leucocyte count and the high fever which made the case appear one of abscess. A leucocytosis of 38,800 per c.mm. is most rare in a case of tumour. I think that it may be explained by the intense pneumonia which we found after death, and it will be remembered that streptococci were found in the sputum. In fact, the patient *did* have septicæmia as well as a rapidly growing and a rapidly degenerating tumour. Still, the leucocytosis was a source of error, and I have no doubt that had the swelling been an abdominal one and exploratory puncture impracticable the patient would have been put to the mental distress of a useless exploratory incision. On the whole, the X ray department was, in this case, more useful to us than the laboratory.

Thirdly, the growth of the subcutaneous nodule, at the site of the exploratory puncture and separated from the main tumour, is interesting. I have known it occur in cancer of the peritoneum with ascites, at the point of paracentesis, but I have not seen it before in sarcoma. However, as secondary subcutaneous nodules may occur on the side of the chest wall in cases of sarcoma of the lung in which no puncture has been made, the position of the tumour at the point of puncture may have been accidental.

Lastly, the sudden appearance of blood and pus in the stools on April 24th, with symptoms suggestive of perforation into the bowel, is of interest, as it again raised the question of abscess for a few days. The post-mortem examination did not reveal the source of this pus, but as the discharge occurred five weeks before death it is quite possible that follicular ulcers may have been present in the colon, and that they may have healed rapidly in spite of the dying condition of the patient; and, seeing the agglutination reaction of the blood with Shiga's bacilli, I believe that this is what actually occurred.

Mansfield-street, W.

ROYAL INSTITUTION.—The eighty-sixth Christmas course of juvenile lectures, founded at the Royal Institution in 1826 by Michael Faraday, will be delivered this year by Dr. P. Chalmers Mitchell, D.Sc., LL D., F.R.S., secretary of the Zoological Society, his subject being "The Childhood of Animals." The lectures will be delivered on the following dates at 3 o'clock: Dec. 28th and 30th, 1911; and Jan. 2nd, 4th, 6th, and 9th, 1912.

SERVICE FOR MEDICAL MEN AT TORQUAY.—The second annual service for medical men and nurses was held at St Luke's Church, Torquay, on Oct. 22nd. There was a good attendance, and an eloquent sermon was preached by Prebendary B. R. Airy. Mr. Airy, in alluding to the work of members of the medical profession, spoke of the advantages of working hand in hand with the parish priest. He stated that from the earliest time the physician had been held in honour, and "to-day no one was more honoured, loved, trusted, and welcomed in every home in England." The collection at the service was given to the funds of the Torbay Hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS.

Deaths under Anæsthesia.—Acute Post-Anæsthetic Bronchitis and (?) Pleurisy.—Persistent Vomiting during Induction of Anæsthesia for Extraction of Teeth.—Oral Airway in Anæsthesia.

A MEETING of this section was held on Nov. 3rd, Dr. W. J. MCCARDIE, the President, being in the chair.

Reports of three deaths under anæsthesia.—(*a*) Fat, flabby, very nervous woman, aged 50, died from respiratory failure during the induction for a proposed abdominal operation for uterine fibroids. Total quantity of anæsthetic used about 1 drachm of ether during the first few minutes and 30 minims of chloroform. Cessation of respiration occurred about seven and a half minutes after commencement of administration, and no spontaneous respiration occurred in spite of all usual remedies and artificial respiration for three hours. During life the patient complained of dyspnœa and palpitation on exertion. Post-mortem: Abdomen distended with uterine fibroids, omentum, and an enlarged and fatty liver. Heart infiltrated with fat, lungs emphysematous and markedly fibrosed. At no time during the administration or at death was there any pallor, dilatation of pupils, rigidity or spasm, or accumulation of mucus in the airway. (*b*) Pale, thin, markedly anæmic woman, aged 49, died from heart failure during induction for a proposed abdominal operation for uterine fibroids. Total quantity of anæsthetic 2 drachms of chloroform and a little ether towards the end of induction. Respiration normal till five minutes from commencement of administration, when seven or eight sighing breaths were taken, when there were wide dilatation of pupils and disappearance of pulse. Post mortem: Old pyonephrosis of kidney, collapse of base of left lung. Heart flabby and thin, but nothing definite. No excess of lymphoid tissue. (*c*) Well-nourished, well-developed girl, aged 15½. Total anæsthetic 4 drachms of A.C.E. administered in a single dose in a celluloid inhaler. Operation for tonsils and adenoids successfully completed and throat sponged out. A little later the patient coughed strongly, breathing ceased, colour became bad, no pulse palpable at wrist. Artificial respiration started and patient made two or three spontaneous attempts at breathing. Pupils were dilated. Post mortem: Marked signs of status lymphaticus.—Several members took part in the subsequent discussion, mainly directing their remarks to the various methods of artificial respiration—Schafer's method and possibly the perflation of the lungs with oxygen being considered the best.

Dr. J. F. W SILK reported a case of Acute Post-anæsthetic Bronchitis and (?) Pleurisy in a man, aged 34, to whom he had administered about 15 ounces of ether by the open method during an operation for radical cure of double inguinal hernia lasting—owing to adhesions, &c.—1¾ hours. No preliminary injection of atropine or other drug was given. The patient ultimately recovered. Dr. Silk was of the opinion that the case was rather one of pulmonary collapse. He reported the case in support of the view that the open method might give rise to troubles practically identical with those which arise with the closed methods.—In the subsequent discussion the frequency of trouble after operations for hernia and abdominal cases was noted and the prior use of atropine insisted on.

Mr. R COLLUM reported a case of Persistent Vomiting in a girl during the Induction of Anæsthesia for the Extraction of Teeth. On the first occasion the patient had had breakfast, and gas and oxygen and subsequently gas alone were tried. The next day the patient had no breakfast, and gas alone and two subsequent doses of ethyl chloride were tried. On the third day ethyl chloride was employed and the last of the teeth extracted. On every occasion and with each drug vomiting occurred.—In the subsequent discussion increasing the pressure of the gas in the bag, previous gargling with dilute carbolic acid, or a small dose of cocaine by the mouth were all suggested as means of preventing retching.

Mr. BELLAMY GARDNER then read a short communication insisting on the routine use in every administration of an anæsthetic of establishing an oral airway by means of a mouth-prop and tongue-clip. He dwelt on the insufficiency of nasal breathing in cases of anæsthesia and suggested that the words "asphyxial death space" be employed in teaching students in order to impress them with the necessity of maintaining a free airway in an unconscious patient.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.—Night Blindness.

A MEETING of this section was held on Oct. 27th, Dr. G. A. SUTHERLAND, the President, being in the chair.

The following cases were shown:—

Dr. J. PORTER PARKINSON: A case resembling General Paralysis of the Insane, in a girl, 9 years of age. The evidence of syphilis was in the maternal history and the remains of an iritis from which she had suffered three months previously. It was considered impossible to state definitely whether the case was one of general paralysis of the insane or one of diffuse cerebral syphilis.

Mr. O. L. ADDISON: Two brothers, aged 9 and 6 years, with Genu Valgum and Hyperextension of the Knees. Both cases exhibited the voluntary production of a noise during flexion and extension of the knee-joints.

The PRESIDENT: 1. Infantilism in a girl 16 years of age, who had the intelligence of a child of 6, at which age growth ceased, rickets appeared, and constipation became very marked. The abdomen was distended, and at times peristaltic waves were visible over the colon; the bowels never acted without aperients or enemata. 2. Extreme Rickets and Infantilism.

Dr. F. LANGMEAD: (1) Sclerodermia with Myositis Fibrosa, previously shown 12 months ago; and (2) Sclerema.

Mr. P. MAYNARD HEATH: 1. Intra-uterine Fracture of the Tibia with much Rarefaction of the Bone around the Site of Fracture. 2. Gigantism of the Forepart of the Foot in a girl six years of age. The deformity was noticed at birth, and at the age of three months an enlarged toe was amputated; since then the forepart of the foot had grown more than the rest of the body, and between the first and third toes there was a very pronounced swelling.

Mr. A. H. PAYAN DAWNAY: Double Third Nerve Palsy due to Acute Poliomyelitis.

Dr. T. R WHIPHAM: Recurrent Unilateral Œdema in a boy 14 years of age.

The following pathological specimens were shown:—

Dr. J. D. ROLLESTON: Diphtheria of the Fauces and the Lower End of the Œsophagus.

Dr. R. SALUSBURY TREVOR: (1) Aneurysm of the Right Coronary Artery, situated in the wall of the right ventricle and opening into the cavity of the right ventricle, associated with non-valvular infective endocarditis; and (2) Congenital Morbus Cordis (Cor Biatriatum Triloculare).

Mr. SYDNEY STEPHENSON read a paper on cases of Night-blindness with Peculiar Conjunctival Changes in Children. The communication dealt with a curious class of case not uncommon during the summer months in institutional children, where white frothy patches on the ocular conjunctiva were or were not associated with symptoms of night-blindness. He had found that in either circumstance the field of vision manifested slight changes, the light minimum was diminished, the fundus oculi showed changes, and lastly, the colour index of the blood was lower than normal. Mr. Stephenson believed the immediate cause of both affections was the dazzling of sunlight, and their remote cause some slight defect of nutrition, as evidenced by the changes he had found in the blood.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION.

Presidential Address.

A MEETING of this section was held on Oct. 27th, Mr. GEORGE H. THOMPSON (Buxton), the President, being in the chair.

After referring to his election as President in a few graceful phrases Mr. THOMPSON delivered his introductory address entitled "Baths and Climate in Relation to Spa Treatment; Some Reflections and Suggestions." He briefly sketched the development of modern spas, and pointed out that it was the first duty of health resorts to study the

peculiar properties of their natural mineral waters and their applicability in the treatment of particular diseases, and subsequently to provide accessory methods of treatment which were often essential to success. He pointed out that the recent discovery of radium had opened up a new field of research in connexion with the physiological action of mineral waters, and the investigations of Professor His gave promise of a real scientific basis being established to explain their activity. He was of opinion that spa authorities in the future would be compelled to provide equipment for treatment by radium emanations, and should be prepared to meet the outside competition of commercial institutes. In conclusion, he referred to the valuable help which had been given to balneology in this country by the Section and by the municipal authorities of the various health resorts, and contrasted this with the State aid provided in France and Germany for the development and maintenance of national spas.

After his address the PRESIDENT invited Dr. MONOD of Vichy to explain to the members of the Section the purport of his mission to this country. Dr. Monod said that he had been sent by the French Government to study the health resorts of Great Britain and to report thereon. He averred that Dr. Neville Wood's paper, "British Health Resorts for Foreign Invalids," which was read before the Section during the past session, had evoked great interest on the continent and was in large measure responsible for the action of his Government. He had been much impressed by the completeness of the therapeutic equipment of the different spas he had already visited, and he thought that many of his countrymen, for whom an entire change of surroundings would prove of the greatest advantage, would find in England resources not available at home. In conclusion, he pleaded that the whole question of spa treatment should be placed on an international basis.

LIVERPOOL MEDICAL INSTITUTION.

President's Address.

THE inaugural meeting of the session of this society was held on Oct. 12th, when an address was given by Dr. T. R. BRADSHAW, the President, on the Prognosis in Valvular Disease of the Heart. He analysed the results of a large number of cases and gave tables showing the number of years during which after the onset of the endocarditis the patients had remained free from any symptoms of heart disease.

Abscess of the Brain.—Wassermann Test for Syphilis.

A second meeting of the session was held on Oct. 26th, the PRESIDENT being in the chair.

Dr. A. NIMMO WALKER read a note on a case of Abscess of the Left Frontal Lobe of the Brain following empyema of the frontal sinus. The diagnosis had been difficult, as the only signs in favour of cerebral abscess had been drowsiness and a pulse of 50 to 60, whilst against abscess there had been rapid cerebration, temperature above normal, absence of vomiting and of optic neuritis, and presence of marked pulsation of the dura mater, but the abscess contained about half an ounce of pus. The patient, who was shown at the meeting, had made a good recovery and apparently had not suffered any mental damage. Dr. Walker asked for opinions on the relative values of the signs of cerebral abscess.—Dr. J. E. MCDOUGALL considered that a plastic operation would not be successful until adequate drainage had been established into the nose so as to bring about the closure of the small opening on the surface which was now present. On the question of the diagnosis of pus retained in the frontal sinus Dr. McDougall laid stress on the tenderness to pressure when applied to the floor of the sinus and the pain so much more marked at night. Skiagraphy, if available, was also useful both in the diagnosis of suppuration and in demonstrating the limits of the sinus.—Mr. E. MALCOLM STOCKDALE remarked that the diagnosis was greatly simplified by the presence of a local lesion (empyema of the frontal sinus), as it also was in certain brain abscesses arising in connexion with suppurative disease of the middle ear, where a definite tract of infection could be traced. Chronic suppurative disease of the frontal sinuses, although it might give rise to serious and fatal complications, was, owing to the absence of all symptoms with the exception of some nasal discharge which might cause no inconvenience, commonly overlooked unless an acute attack supervened. Mr. Stockdale suggested the obliteration of the frontal sinus as the proper treatment since active disease was still present.—Dr. W. B. WARRINGTON said that the inferences from the state of the dura might be misleading; pulsation was not apparent in cases in which exploration failed to reveal any cause of increase of pressure. Dr. Walker had followed the best method of treatment and diagnosis because he had not been content until each new symptom had received an adequate explanation.

Mr. R. C. DUN showed a patient, aged 11, with Cervical Ribs, demonstrated by radiography. No symptoms referable to the ribs were complained of.

Dr. FREDERICK P. WILSON read a paper on the Wassermann Test for Syphilis. He gave a brief account of the principles on which the test was based, and mentioned some reasons for discordant results. He drew attention to the unstable nature of the materials used in the test and the consequent necessity for their frequent restandardisation. He considered that all apparatus hitherto issued for use in the consulting-room was most unreliable. For the proper performance of the test a well-equipped laboratory was still essential. The diagnostic value of the test in the various stages of syphilis was next discussed and the influence of the treatment on the strength of the reaction pointed out. In parasyphilitic diseases there was no parallelism between the Wassermann test of the cerebro-spinal fluid and the globin reaction or lymphocytosis. The Wassermann reaction of the cerebro-spinal fluid was negative unless the syphilis had attacked the nervous system. The effect on the test was reviewed and the opinion expressed that salvarsan affected the test more rapidly than mercury, but that several injections might be necessary. It was not yet possible to say that a patient with no symptoms other than a persistent Wassermann reaction after thorough treatment was not cured, but the evidence was strongly in favour of such a conclusion. The test was not absolutely specific, but must rather be regarded as an adjuvant to the clinical examination.—Dr. R. W. MACKENNA said that he had found Wassermann's own method the best. He had obtained the reaction at the end of the third week in the primary stage. In the secondary stage a large number of the cases gave the reaction. In the third stage he had found that those cases which showed evidence of multiple lesions and which gave a history of irregular or infrequent treatment and frequent recrudescences almost always gave a strongly positive reaction. He had examined four cases of parasyphilis, and in each case had found a positive reaction. In a case of congenital syphilis in which no symptom of the disease manifested itself until the patient was over 25 years of age he had found a strongly positive reaction. There was no doubt that salvarsan was the most potent remedy for converting a positive into a negative reaction. After a preliminary course of mercury the conversion of a positive into a negative reaction followed more certainly. Where the patient received two injections of salvarsan separated by a vigorous course of mercury the reaction usually became negative after three or four weeks.—Dr. FRANK H. BARENDT considered that in doubtful cases the view of the clinician should prevail.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

President's Address.—Exhibition of Cases—Tabes with Severe Gastric Crises treated by Resection of Nerve Roots.

THE first meeting of the ninety-first session was held on Nov. 1st, Dr. BYROM BRAMWELL, the retiring President, being in the chair.

Dr. NORMAN WALKER showed a man who was the subject of an Antipyrin Rash. The eruption consisted of round, dark red, slightly elevated spots, chiefly on the hips, though isolated spots occurred on other parts of the body. The patient complained much of the fiery pricking itching sensation which was present in the spots and which had lasted for five years. Dr. Walker thought at first that it might be an early stage of mycosis fungoides. On closer inquiry, however, it was found that the man was a sufferer from migraine and had taken for many years migrainine in order to relieve

the headache. Migrainine consisted of 90 per cent. antipyrin with 10 per cent. caffeine. The eruption closely resembled that figured by Jacobi in his atlas as due to antipyrin.

Sir THOMAS R. FRASER showed a case of Syringomyelia with Unilateral Hyperidrosis. The case was that of a man, aged 22, unmarried, admitted to the Royal Infirmary on July 15th, 1911, with symptoms of spastic paraplegia, affecting especially the left leg. This condition had commenced about Christmas, 1910. The symptoms were clearly present on his admission to Ward 26 and persisted for several weeks thereafter. They subsequently, however, gradually abated and were at present very slight, though perhaps rather aggravated on this occasion through excitement. When he was first examined it was also found that his sensibility was definitely modified. The sensibilities to weight, touch, and locality were sharp and healthy, but over a large skin area thermal and pain sensibility were either entirely absent or defective, the lines of demarcation between normal and defective sensibility being fairly distinct. The localisation was almost symmetrical. Among the parts not involved were the head and neck. It had been observed that excessive sweating frequently occurred on the right half of the scalp, face, and neck, while the left half appeared quite dry. This unilateral hyperidrosis had existed for many years. It was readily induced by mental excitement, and pilocarpine caused sweating over those parts many minutes before it appeared on the corresponding parts on the left side of the head or elsewhere in the body.

Mr. H. ALEXIS THOMSON showed: 1. A case of Short Circuiting for Chronic Tropical Dysentery after failure to cure by appendicostomy. The patient was a man, aged 30, who had suffered from malaria and dengue in Singapore and the first attack of dysentery in Shanghai early in 1908. He had improved under change of air, but then relapses occurred. There were sloughs as well as pus in the motions, and he had lost over 2 st. in weight. Appendicostomy was performed on Dec. 29th, 1910, with subsequent slight improvement. Ileosigmoidostomy was performed on May 30th, 1911, and improvement at once set in; in three months he had put on 1½ st. to his weight. 2. A case of Ulcerative Colitis for which appendicostomy was performed 22 months ago. The patient, a man aged 27, had suffered from colitis for four years. He improved with four months' treatment in the medical wards of the Royal Infirmary, but then relapsed. His colitis was of the ulcerative type, with a large amount of blood in the motions. Great benefit was derived from saline irrigations through the appendix, and these still had to be continued, as he was subject to fits of mental depression brought on by his condition.

The PRESIDENT then delivered his Valedictory Address. After returning thanks to the members Dr. Byrom Bramwell gave a summary of the work which had been brought before the society during the two years in which he had held office. He stated that contributions, both as regards patients, exhibits, and papers, had been contributed fairly equally by physicians and surgeons, and he paid a tribute to the general practitioners who had taken a large share in the work of the meetings. He said that the financial statement was entirely satisfactory and that the balance was greater than at the corresponding period of last year. He thought that the society would gain great advantage if the meetings could be held in the Royal Infirmary, as large numbers of interesting cases could then be shown. Dr. Bramwell noted that the death-roll had been particularly heavy during his term of office; one honorary member, Dr. Hughlings Jackson, had been removed by death. He was the greatest of neurologists during his life and was the first who had demonstrated clinically and pathologically the motor areas of the brain. One corresponding member, Dr. Pavy, had also just recently died. Of the ordinary members, 14 had been removed: Dr. George Skene Keith, who was born in 1819 and lived until 1910, had been admitted a member in 1845. He was the last survivor of the party who inhaled chloroform round the table of Sir James Y. Simpson. At one time he had a great practice, but was now better known through his two books, "A Plea for a Simpler Life" and "Fads of an Old Physician." When he was 78 years of age he visited Spitzbergen along with his daughter, and two years later he by himself visited Burma, although the cataract which was operated upon when he was 82 years was already advancing. Dr. John Smith, born in 1825, died in 1910, became a member in 1856, and President in 1887. He was a remarkable man in many ways; he was the foremost surgeon dentist of his time; was one of the originators of the Edinburgh dental school; and one of the founders of the Hospital for Sick Children. It was not, however, as a professional man that he was so much admired as on account of his remarkable and loving personality. He was a skilful musician, song writer, and artist; was the author of three pantomimes, and the secretary and bard of the Æsculapian Club. Dr. Joseph Bell, born in 1837, died on Oct. 4th, 1911, was admitted a member in 1882, and was President in 1891. He did splendid work in connexion with many of the philanthropic institutions of the city, and held for many years the position of assessor to the University Court. For 23 years he was the capable editor of the *Edinburgh Medical Journal*. Dr. Andrew Smart was born in 1824 and died in March, 1911. The same year as he was admitted a member (1865) he discovered the cause of rinderpest, and was the first to demonstrate living organisms in living tissues. Dr. Claude Muirhead, born in 1836, died in 1910, was a distinguished physician who did valuable work in the Royal Infirmary, and was one of the greatest authorities on life assurance. Dr. Peter Maclaren, born in 1837, died in 1911, was admitted a member in 1866. He was an able practitioner and surgeon, and was much beloved on account of his upright honest disposition. All these had lived long beyond the allotted span, and while we lamented their demise their transition was natural. It was otherwise with Dr. Alexander Bruce, who, born in 1854, died when only 57 years of age. He was cut off in the full zenith of his powers. His death was a great loss to the Edinburgh Medical School and to science and medicine generally. He was a distinguished neurologist and much of his best work had been brought before this society. Thoroughness, painstaking accuracy, and great reliability were his chief characteristics. Dr. Byrom Bramwell alluded to the other deceased members in feeling terms.

The newly-elected President, Mr. J. M. COTTERILL, having taken the chair,

Dr. BYROM BRAMWELL (along with Mr. ALEXIS THOMSON) communicated a paper on "A Case of Tabes with severe Gastric Crises of many years' duration, in which Section of the Posterior Nerve-roots had produced Benefit." He said that the very persistent and severe gastric crises were completely relieved by division of these nerve roots. The patient was a man, aged 33 years, who had been under observation for a number of years and who had been shown at a meeting of the society. The man had been perfectly healthy until 1901, when he developed an ordinary Hunterian hard chancre. Ten months later he began to suffer from ataxic pain in the stomach with vomiting. These attacks became increasingly severe until the time of the operation. The presence of gastric crises within ten months of the primary sore and the early age of the patient (24) were very rare occurrences. It was suggested that he had been the subject of hereditary syphilis, but there was no ground for believing this. He possessed no stigmata of hereditary syphilis; his family history was good, both parents were alive, as were three brothers and two sisters, all in the best of health; no deaths had occurred in the family, and his mother had had no miscarriages. The first symptoms of tabes developed within ten months, and one year later his sight became dim, and he became completely blind five years ago. He had severe lightning pains in his legs, his bladder became affected, and the right knee showed Charcot's joint disease. There was comparatively little ataxia before the onset of blindness, but subsequently it became excessively marked. This succession was contrary to the statement of Benedickt that optic atrophy had a retarding influence on tabes. The gastric crises continued to recur at irregular intervals until March, 1911; he was never longer than nine weeks without an attack, however; obstinate sickness lasted for several days—18 on the last occasion—during which he became greatly emaciated and passed little or no urine. He suffered great pain and distress; many remedies were tried without effect and even morphia afforded little relief. Dr. Bramwell asked Mr. Thomson to divide the posterior roots of those nerves corresponding to the gastric area. The operation was performed on March 17th, 1911; the cerebro-spinal fluid escaped as if under pressure, and slight adhesions bound the cord to the

meninges and obscured the view of the posterior roots. The posterior nerve-roots corresponding to the seventh to tenth pairs were resected. The patient gradually recovered, though on account of his low vitality the wound was long in healing. He had absolutely recovered from the gastric crises and the lightning pains in his legs had not recurred; perhaps the operation had a psychical effect in curing the latter. Other cases which had been described had given equally satisfactory results. Dr. Bramwell thought that this was the first case which had been operated upon in Scotland. The general health of the patient had also greatly improved, and he asserted that he walked better.—Dr. GEORGE A. GIBSON, Dr. EDWIN BRAMWELL, Dr. H. M. CHURCH, and Dr. K. M. DOUGLAS took part in the discussion, and Dr. BRAMWELL replied.

The following office-bearers were elected for the session 1911–12:—President: Mr. J. M. Cotterill. Vice-Presidents: Mr. Charles W. Cathcart, Dr. John Playfair, and Dr. Alexander James. Members of Council: Dr. T. J. Thyne, Dr. Edwin Bramwell, Dr. R. J. Johnston, Dr. George Hunter, Dr. James Ritchie (secundus), Dr. Francis D. Boyd, Mr. J. W. Struthers, and Mr. George L. Chiene. Treasurer: Dr. J. W. Dowden. Secretaries: Mr. Alexander Miles and Dr. J. S. Fowler. Editor of Transactions: Dr. D. Chalmers Watson.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 3rd in the society's rooms, West London Hospital, Mr. W. McAdam Eccles, the President, being in the chair.—The following cases were shown: Dr. P. S. Abraham: Case of Bazin's Disease.—Dr. Seymour Taylor: (1) A case of Aortic Aneurysm; and (2) a case of Aortic Regurgitation.—Dr. E. A. Saunders: (1) A case of Diabetes in a child 3 years old; and (2) case of Rheumatic Nodules in a child of 4.—Mr. J. G. Pardoe, with Dr. Saunders: Costo-transversectomy for Tuberculous Abscess of Spine.—Mr. N. Bishop Harman: (1) A case of Bi-temporal Hemianopsia, probably pituitary growth, no acromegaly; (2) case of Right Homonymous Hemianopsia, probably due to a lesion of the occipital lobe; and (3) case of Monocular Ptosis with jaw-winking associated movement.—Dr. Frederick S. Palmer: Case of Cerebral Neoplasm with Jacksonian Epilepsy; trephining and result.—Dr. Palmer, with Mr. E. Laming Evans: A case of Pressure Paraplegia from Pott's Disease; laminectomy, followed by considerable improvement.—Mr. H. Tyrrell Gray: (1) Late Result of Arthrectomy of the Knee-joint for Tubercle; and (2) case of Perforating Injury of the Abdomen.—Dr. Harold Pritchard: Case of Splenic Anæmia.—Mr. R. B. Etherington-Smith: A case of Cirsoid Aneurysm of the Orbit.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 26th at the Edgar Allen Medico-Mechanical Institute, Dr. Ernest Knight, the President, being in the chair.—The Methods of Mechanical Treatment were demonstrated by Dr. R. G. Abercrombie, medical superintendent. The nature of the cases demonstrated were as follows: 1. Osteo-arthritis. The most favourable cases were those in which the acute phase had passed. The objects were to increase the mobility of the joints, improve the muscular strength, and correct deformities. The range of movement which could be performed without pain was ascertained, and this was gradually increased day by day. The results were improved if the treatment was combined with ionic medication. One case, a man, had been a helpless cripple. After three months' treatment he could dispense with his crutches and walk with a stick. His arms could now be freely raised, and the deformities had been ameliorated. His general health had greatly benefited. 2. Fibrous Ankylosis of the Hips. The range of movements had been much increased. 3. Rigidity of Fingers after Lacerated Wound involving the Tendons. Attention was drawn to the use of Martin's bandage in such cases. The bandage was applied round the wrist and over the fingers so as to flex them forcibly. Passive congestion was caused in the parts not pressed on by the bandage. Pain was not felt while the bandage was in position, but was felt after its removal. 4. A severe case of Neurasthenia in a man aged 52. This patient derived great benefit from regular and properly ordinated exercise. Special attention was paid to improving the respiratory powers and remedying constipation by strengthening the abdominal muscles. Vibrations were useful in alleviating the distressing cranial subjective symptoms. 5. Wrist-drop in a boy, due to fracture of the lower end of the humerus. After one week's treatment extension was much improved; this was brought about by what was known in Sweden as "eccentric movements." 6. Hemiplegia. The tendency to contractures might be to some extent obviated. 7. Limitation of Movement Following Dislocation of the Shoulder-joint. The function of the joints had been almost completely restored. 8. Three cases of Injury to the Back. One was a partial fracture of the spine, another of traumatic lordosis, and the third a case of "wricked back," with severe symptoms but no physical signs. All the cases showed great improvement after treatment, which consisted of mechanical and gymnastic treatment and massage. Attention was drawn to the treatment of hyperæsthesia by light stroking in the direction of the venous flow. Some cases of injury to the back with severe symptoms but no physical signs have proved intractable to mechanical treatment. 9. Limitation of Movement in the Ankle after Fracture. The mobility of the joint was almost fully restored.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 25th, Dr. F. H. Jacob, the President, being in the chair.—Dr. W. Aldren Turner (London) delivered the inaugural address of the society's session on Recent Views upon Neurasthenia, Hysteria, and Allied Neuroses. He referred in the first place to what had been designated "the partial passing of neurasthenia" during the past decade. The closer study of this malady by the aid of psychiatrical methods had permitted the elimination from it of several pseudo-neurasthenic states. The commonest among these were the recurring attacks of depression in adult life. These were, in the majority of cases, mild forms or "shadowy imitations" of recurrent melancholia (manic-depressive psychosis of Kraepelin). Others were the psycho-neuroses of puberty and adolescent life, some of which were cases of dementia præcox, but the majority were cases of psychasthenia. A further elimination should also be made of the "anxiety neurosis" of Freud as being a condition essentially of an acquired nature, and based solely upon a series of injuries and influences affecting the sexual life. The lecturer then went on to describe the essential features of true neurasthenia or "nervous exhaustion"; the relation to it of the symptoms produced by excessive physical effort, as in running, cycle racing, and mountaineering; and the symptoms and causation of hypochondriasis. He emphasised the necessity of the mind, or "psyche," being affected in true neurasthenia. The second part of the address was devoted to a summary of Freud's views upon the etiology of hysteria, the obsessions and morbid fears, with a description of the method of "psycho-analysis" and its value as a psycho-therapeutic agent. The general view was expressed that in psycho-analysis the physician had received a further aid towards the treatment of cases which had long resisted ordinary therapeutic methods. Many methods were now in the hands of physicians for the cure of hysteria and allied affections. Hypnotic suggestion was no doubt of value in a certain type of case, such as drug habits and sexual perversions; therapeutic conversation as practised by Dubois was also useful in mild and early cases of psycho-neuroses, and psycho-analysis would no doubt in the future prove of value in certain types of cases. As the method, however, was slow and often wearisome, inapplicable below a certain level of intelligence, and liable to place sexual matters in the causation of functional nervous disease upon a pinnacle which further investigation might not entirely endorse, it was unlikely to receive that general adoption which some of its supporters claimed for it.

DONATIONS AND BEQUESTS.—Mrs. Godfrey Walker, of Northbrook Park, Devon, has given £1000 to endow two cots in the Children's Ward of the Royal Devon and Exeter Hospital in memory of her late husband and sister.—The late Mr. C. B. Hare, of Clifton, has bequeathed £1000 to the Bristol General Hospital, £300 to the Bristol Royal Infirmary, and £100 to the Bristol Eye Hospital.

Reviews and Notices of Books.

Quinquennium of Medicine and Surgery, 1906–1910. Edited by J. W. BALLANTYNE, M.D. Edin., F.R.C.P. Edin. Edinburgh: William Green and Sons. 1911. Pp. 411. Price 10*s.* 6*d.* net.

ADVANCES in both theory and fact take place so rapidly nowadays in medicine and surgery that it is impossible for any one man to keep abreast of them all. Hence the need for the various year-books and digests, in which are collected and collated the various improvements, alterations, new theories, new or revived methods of treatment, and other matters that are constantly bringing about alterations which must be borne in mind by the medical profession.

The book now before us deals with a period of five years, and we congratulate the editor upon the manner in which he has carried out his work. In most cases he simply gives a digest of the original worker's opinions or researches on the matter in hand, but when he submits his own opinion it is always from much knowledge and with a due sense of responsibility. The collating and condensation of the various papers and reports have evidently been carried out with great care, and the book contains digests of very modern and little known subjects. For instance, we find a careful and full analysis of Freud's work in psycho-analysis—a subject of great importance, and one, we think we may say, but little known to the majority of medical men, for which reason attention has been directed to it in our columns on several recent occasions. To take another matter, not new, but one which is constantly in a state of flux—namely, immunity. Anyone referring to this book will find a very clear exposition of the various theories and problems connected with the subject which will go far to make a complicated problem clear. Other important subjects about which little is known are tuberose sclerosis, pancreatic infantilism, and the chloride-free treatment of nephritis. As a point in the history of medicine it is interesting to note that the first English court physician, John of Gaddesden, counselled his patients who were suffering from dropsy to avoid eating a quantity of salt, and he especially mentions a particular kind of bread as one to be avoided, "quia nimis est salsus." The date of John's death was 1361.

Dr. Ballantyne has produced a work that will undoubtedly be of great service to the busy practitioner, and although we believe that this volume is the first, we earnestly trust that it will not be the last, but that 1916 will see the publication of another.

The Wassermann Sero-Diagnosis of Syphilis in its Application to Psychiatry. By Dr. FELIX PLAUT, Scientific Assistant in the Psychiatric Clinic of Munich. Authorised translation by SMITH ELY JELLIFFE, M.D., Ph.D., Professor of Psychiatry, Fordham University, New York; and LOUIS CASAMAJOR, A.M., M.D., Assistant, New York Neurological Institute. New York: The Journal of Nervous and Mental Disease Publishing Company. 1911. Pp. 188. Price $2.00.

THIS book constitutes the fifth in the "Nervous and Mental Disease Monograph Series." It contains an examination of the Wassermann reaction as a factor in the diagnosis of mental disease, and is a critical, scientific, and useful contribution to the literature of the subject. Dr. Plaut is a pupil of Professor Wassermann, to whom he dedicates his book, and some of the work recorded in it has been carried out in collaboration with him.

The first chapter gives within short compass an admirably lucid and critical review of the development of the Wassermann reaction and of some of the various modifications to which it has been subjected. The difficulties introduced in its biological interpretation from the fact that complement fixation can be obtained with syphilitic serum by the agency of lipoids, such as lecithin, as well as with aqueous extract of syphilitic organs, are carefully indicated, and Dr. Plaut concludes that a completely satisfactory explanation of the nature of the reaction has not yet been found. He points out that Wassermann still affirms that extract of syphilitic organs is necessary for an absolutely trustworthy sero-diagnosis of syphilis, a view which, on the basis of some personal comparative trials of different methods, Dr. Plaut confirms. A chapter is devoted to a consideration of the clinical specificity of the method, and it is suggested that the sporadically occurring positive reactions in the so-called normal control material are due to syphilitics who know nothing about their infection.

The clinical investigations upon which the book is based comprise an examination of the blood, and in many instances of the cerebro-spinal fluid also, for the Wassermann reaction in cases of syphilis without complication in the nervous system, cases of general paralysis of the insane, of cerebral syphilis, of tabes with and without psychoses, and of feeble-mindedness upon a hereditary syphilitic foundation. It was found that none of the cases of syphilis without nervous involvement gave a positive reaction with the cerebro-spinal fluid, although a reaction might be obtained from the blood. In general paralysis 156 patients were tested for the reaction in the blood, and all were positive. The cerebro-spinal fluid was examined in 147 cases, with positive results in 139, doubtful in 2, and negative in 6. In tabes without psychic symptoms Dr. Plaut was able to investigate only 16 cases, and is therefore unable to generalise, but he found some cases which did not give a positive reaction in the blood, and in the cerebro-spinal fluid the reacting substances are not met with so frequently as in general paralysis. Some interesting observations are recorded on the influence of mercurial treatment upon the reaction. The results of comparative serological and cytological investigations of the cerebro-spinal fluid in the various conditions studied are given in the concluding chapter. A full bibliography and index complete a highly instructive and original monograph.

Lehrbuch der Therapie innerer Krankheiten. Für Aerzte und Studierende. I. Band. Edited by Dr. PAUL KRAUSE and Dr. CARL GARRÈ. Jena: Gustav Fischer. 1911. Pp. 758. Price 11.50 marks.

THIS volume deals in great detail with the principles upon which the various forms of therapeutic methods are founded. It is divided into 18 chapters, and several contributors take part in its production. The first chapter, by Dr. M. Matthes, of Marburg, deals with diet in disease. The heat and power-producing qualities of the various constituents of food matters are carefully discussed, and the influence on morbid processes of the organic and inorganic components is fully indicated. The use of various articles of diet in connexion with disease then receives attention, the advantages of meat, eggs, milk, cereals, and so on, being duly pointed out, as also are their contra-indications. The various methods of administering drugs are considered by Dr. R. Magnus, of Utrecht. In addition to the ordinary ways in which medicaments may be given the intramuscular and intravenous methods are described, as is also the injection of substances into the serous cavities.

Dr. J. Strasburger, of Bonn, writes on hydrotherapy and thermotherapy, and in an interesting manner gives a description of the many forms of baths that are employed. This chapter concludes with a complete list of the places in Germany where these measures are carried out. Climatic treatment of disease is considered by Dr. F. Frankenhäuser,

of Berlin, who indicates the various maladies which are likely to be favourably influenced by treatment at the German resorts. Subsequent chapters are devoted to a description of other therapeutic measures, such as compressed and rarefied air, inhalations, massage, gymnastics, mechanical orthopædics, electro-therapeutics, the use of the Roentgen rays, the employment of radium, the influence of suggestion and a brief survey of the value of sera and vaccines.

The whole volume forms interesting reading and contains a large amount of information.

American Practice of Surgery. Editors, JOSEPH D. BRYANT, M.D., LL.D., and ALBERT H. BUCK, M.D., of New York City. Complete in eight volumes. Profusely illustrated. Vol. VIII. New York: William Wood and Co. 1911. Pp. 1146. Price $7 per volume.

THE final volume of this important System of Surgery is worthy of those which have preceded it. In it are gathered together all the subjects hitherto untreated. It commences with intrathoracic surgery, excluding the surgery of the heart and œsophagus; this chapter has been written by Dr. Joseph Ransokoff and Dr. J. Louis Ransokoff, of Cincinnati, and it contains a good account of Sauerbruch's chamber. The skiagrams of intrathoracic conditions are very satisfactory, and though some of the descriptions of operations —for instance, thoracoplasty—are very brief, on the whole the subject is satisfactorily treated. The surgery of the spleen has been entrusted to Dr. A. Esslemont Garrow, of Montreal, who has fulfilled his task well. Dr. James Bell, of Montreal, has written the chapter on surgical diseases and wounds of the kidney and ureters. He describes their anatomy and physiology, and gives a short account of the diagnostic methods available in such cases. As to moveable kidney, Dr. Bell advocates operation for all pronounced cases, regardless of the cause, unless there is also a general enteroptosis.

Dr. George David Stewart, of New York City, has contributed the chapter on the surgery of the pancreas. He does not attach much value to the Cammidge reaction, and thinks that the test should always be controlled and confirmed by other and more trustworthy procedures. The same author has written on the surgery of the liver and gall-bladder. In opposition to the more generally received view, he does not consider that infection of the bile-ducts through the portal vein is very common. He discusses the question of cholecystectomy in place of cholecystostomy, but he does not pronounce a judgment.

Dr. A. Hugh Ferguson, of Chicago, has supplied the article on the surgery of the urinary bladder and prostate. He holds that the Bergenheim operation, or Peters's operation, or the extraperitoneal implantation of each ureter separately with a piece of bladder into the rectum, is the best surgical procedure for the treatment of ectopia vesicæ. For the removal of a hypertrophied prostate the author prefers the median perineal incision, and he advises that almost all cases should be explored through the perineum, and then if it be found that certain portions of the hypertrophied prostate cannot be removed by that route, the operation can be completed by the suprapubic incision. The surgery of the ovaries and Fallopian tubes has been written by Dr. Benjamin R. Schenck, of Detroit, Michigan, and the surgery of the uterus by Dr. John B. Murphy and Dr. Frank W. Lynch, of Chicago. These articles are excellent and fully abreast of the knowledge of the present day. Dr. Lewis S. McMurtry, of Louisville, Kentucky, has contributed the chapter on extrauterine pregnancy, as well as that on Cæsarean section and its substitutes.

A very important chapter is that dealing with the law in relation to the practice of surgery, and though it has to do mainly with the laws of the United States there is much that is applicable to other countries. The section dealing with the surgeon as a witness in a court of law is likely to prove of general utility. Dr. Christian R. Holmes, of Cincinnati, is responsible for the chapter on hospitals and hospital management, which gives a very readable account of a most important subject.

Major Charles Lynch, of the Medical Corps of the United States Army, has contributed the article on military surgery. Much of the material is necessarily based on the experience of the Russo-Japanese war. Surgeon-General Charles F. Stokes, of the United States Navy, has supplied the chapter on naval surgery, and it contains some good plans of the arrangements on board ship for the medical department. Illustrations showing the extensive wounds in present-day warfare at sea are given. Railroad surgery is of even more importance in Canada and in the United States than in this country, because of the greater length of line and the greater frequency of accidents; the subject has been entrusted to Dr. James Alexander Hutchinson, of Montreal, who has treated it ably.

In an appendix Dr. J. E. Sweet, of Philadelphia, has supplied a chapter on the relation of blood pressure to surgery, in which are discussed the various factors that influence blood pressure, especially in operations.

Das Roentgenverfahren in der Chirurgie. By Dr. ALBAN KOHLER, Wiesbaden. Berlin: H. Meusser. 1911. Pp. 79. Price M. 5.75.

THIS is an excellent short treatise on the use of the X rays in surgery; it is illustrated by a number of actual photographs of the radiographs, and though these have been very much reduced in size, the amount of detail to be seen is so great that nothing is lost. We do not remember having seen more perfect examples of photographic reproduction. There are many important details in the chapter on technique that will be valuable to even experienced radiologists, and special attention must be drawn to the sections on fractures and displacements and the diseases of bone. Except for recording the passage of a bismuth meal, the author does not think that instantaneous radiography has any special advantage in purely surgical work. Among some of the more novel contents of the work are to be noted the fact that the method has been used for the detection of alterations in the muscles and other soft tissues; there is also a useful suggestion for assisting the detection of gall-stones. This little book is sure to be of interest to all who are concerned in X ray work.

Sammlung Anatomischer und Physiologischer Vorträge und Aufsätze. Herausgegeben von Prof. Dr. E. GAUPP und Prof. Dr. W. TRENDELENBURG. Heft 15. (Zweiter Band, Heft 2.) *Blutkörperchen und Wanderzellen.* Von Prof. Dr. FRANZ WEIDENREICH in Strassburg. Jena: Gustav Fischer. 1911. Pp. 65. Price M. 1.50.

Mephistopheles said to Faust, "Blood is a juice of quite peculiar kind," a remark which finds wider application with every advance in our knowledge of this fluid. The author does not confine his remarks merely to the cells of the blood as they occur in the blood stream; on the contrary, he deals with such of these as wander out of the blood-vessels and occur in other fluids and tissues of the body in both vertebrates and invertebrates. The result is that we have a thoroughly reliable monograph on blood corpuscles and "wandering cells" by one who himself has devoted much study to this subject. After describing what is included under the terms blood and lymph cells, he considers their distribution and origin, and the phylogenetic derivation of the vascular system and its cells. To the red corpuscles, which occur also in some invertebrates, he applies the term

"pneumocytes." It is to be noted that all respiratory substances, however, are not coloured. There is a form of achroglobuline present in the blood of certain molluscs which acts as an oxygen carrier and is colourless. Colourless pneumocytes in invertebrates are next considered, and then the various forms of leucocytes in vertebrates. Rightly, we think, the author points out that the mere staining capacity of granules in certain of these cells has been over-estimated, more especially when so-called eosinophile or neutrophile granules are compared in the leucocytes of vertebrates and invertebrates. Some fish possess only non-granular leucocytes. It would almost seem as if certain blood cells do not become physiologically active until they undergo a morphological degeneration. Very full consideration is given to the red corpuscles and their lipoid membrane in animals and man. Finally, leucocytes—the most ubiquitous cells of the body—and the origin and regeneration of the blood cells are considered.

This is an excellent monograph, a careful *résumé* of the subject, and should prove useful to physiologists, zoologists, and pathologists. A list of the literature is appended.

Die Hernien und ihre Behandlung. (*Hernias and their Treatment.*) Von O. BORCHGREVINK, Oberarzt des Diakonenhospitals in Christiania. Mit 40 figuren im text. Jena: Gustav Fischer. 1911. Pp. 312. Price, paper, 5 marks; bound, 6 marks.

THIS is really the second edition, though it is the first which has appeared in German. The author tells us that one reason for his writing the book was the wish to provide for medical men in country districts where there is no possibility of calling in help from outside, detailed instruction concerning the performance of the operation for strangulated hernia. In a country so sparsely populated as Norway it is especially necessary that the country practitioners should be able to act in such emergencies. The book is written very clearly, and it should be useful to those who desire a full account of hernia and its treatment. Useful tables are given of the results of treatment in a large number of cases, and a scheme is provided for the examining and recording of a case of hernia. The illustrations are on the whole good.

Die Pathologie des Wachstums im Säuglingsalter (in ihrer Beziehung zu allgemein biologischen Problemen und in ihrer Bedeutung für die Klinik). Von Dr. ERNST SCHLOSS. Mit 49 Kurven in Text und auf 2 Tafeln. Berlin: S. Karger. 1911. Pp. 155. Price, paper, 5 marks.

THIS is an interesting and elaborate piece of work on the pathology of growth in the infant and its relations to main biological problems such as those of nutrition in general. The work was done largely in the Foundling Hospital of Berlin, in Rummelsburg, and it is so set forth that it is very difficult to give a short readable *résumé* of the author's results. Moreover, there are a considerable number of definitions to be attended to. The significance of feeding in relation to the pathology of growth is first dealt with, including the action of simple foodstuffs, such as carbohydrates, on the increase in weight, and here the author works in the problems of osmosis and the colloid chemical theory of the combination of water. Next he deals with the clinical phenomena of pathological growth, treating first of anomalies from the point of view of their time relations, i.e., at what period of growth occur accelerated, delayed, or arrested growth. Under the heading "dyskrasia," or the disturbances of correlative development, he includes rickets, Barlow's disease, myxœdema, acromegaly, and so on. As regeneration is intimately related to growth a chapter is devoted to regeneration, or, as the author calls it, "reparation." The third chapter treats of the general pathology of the phenomena of growth in the suckling, dealing more especially with the pathogenesis of these anomalies.

This is a work that should command serious study from those who devote their attention to the pathology of the diseases and anomalies incident to infant growth, and to these we cordially commend it, though to read and understand it requires very considerable patience and application, as well as a knowledge of what has been done on this subject, more especially in Germany.

LIBRARY TABLE.

La Maladie de Little: Étude Anatomique et Pathogénique. By Mme. LONG-LANDRY, Ancien Interne des Hôpitaux de Paris. Paris: H. Delarue. 1911. Pp. 147.—In view of the uncertainty that still prevails as to the exact nature and symptomatology of what is called on the continent Little's disease, a disease for which many synonymous terms exist, a *revue d'ensemble* is very welcome, particularly considering the fact that the results of the pathological examination of four cases provide excellent material on which to base conclusions. Madame Long-Landry shows that lesions differing in their localisation and nature may produce the syndrome, and that cerebral, cerebro-spinal, and spinal varieties may be distinguished. The pathogenic factors are of two sorts—infective agents operating in intra-uterine life and traumatisms at birth. The imperfections of voluntary movement which all cases show are the sequel to the lesions of the nerve centres at an early stage in their development, and represent an attempt at adaptation on the part of an injured nervous system. All congenital diplegias, whatever their anatomical basis, may be united under the term Little's disease. An excellent bibliography and well-reproduced drawings and photographs add to the serviceableness of this thesis.

Domestic Hygiene for Nurses. With so Much of Physics and Chemistry as are Necessary to the Reasonable Understanding Thereof. By FRED. J. SMITH, M.D. Oxon., F.R.C.P. Lond., Physician to the London Hospital, and Examiner in Elementary Hygiene to the Nursing Probationers. With 18 illustrations. London: J. and A. Churchill. 1911. Pp. 164. Price 2*s.* 6*d.* net.—This book has been written to explain the elements of hygiene, more especially from the point of view of probationer nurses undergoing their course of training in a general hospital. It differs from an ordinary text-book in that it embodies a sufficient elementary knowledge of the laws of heat, light, and chemistry, which helps to clothe with interest the subject of hygiene. The author writes also in a manner suitable to the needs of his particular audience. He starts by considering the nature of matter and its forms, and then consecutively considers the physics of heat, light, air, and water. The chemistry of hygiene is next discussed, and finally the theory and practice of domestic hygiene, based on physics and chemistry, are set forth in a clear and concise way. The book is well printed, the illustrations are carefully selected and well reproduced, and there is an ample index.

A Miscellany of Verse. By JOSEPH J. MOONEY. Birmingham: Cornish Bros., Limited. 1911. Pp. 80. Price 2*s.* 6*d.* net.—This is a little book of verses by a member of the medical profession which will not be without attraction to those who like to see something of the physician outside medicine. Several of the lyrical forms are represented, the rondel and the sonnet appealing especially to the author. There are metrical translations from German and Latin authors, among which last are to be found Catullus, Statius, Hadrian, and Ausonius. The lines of Ausonius on Lais's Mirror are gracefully rendered. The *Ne sit Ancillæ* of Horace appears in English dress, but one

is rather startled to find Xanthias Phoceus addressed with the Irish prefix "O'" (doubtless a printer's error); and Briseis and Atrides would have got us into trouble in the days of our youth. There are some mediæval Latin students' songs, and some hymns, both original and translated.

The Dinner Calendar: A Dinner for Every Day in the Year. Compiled by MAY LITTLE, First-class Diploma, late Staff Teacher of the National Society's Training School of Cookery, London. London: T. Werner Laurie. 12 sheets. Price 1*s.* net.—Each of these 12 sheets gives a separate menu for every day of the month, consisting of a soup, fish, joint, entrée game or poultry, with sauce and two vegetables, sweets, and cheese or a savoury. They are evidently arranged with a view of relieving housekeeping from the monotony and lack of appetising quality that are more often the result of bad management than of necessary economy. We can heartily commend these sheets to managing housewives with æsthetic tastes but limited means, provided they are gifted with a culinary capacity; for these are merely menus, not cookery receipts.

JOURNALS AND MAGAZINES.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., Professor ALEX. MACALISTER, Professor ARTHUR THOMSON, Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON. Vol. XLVI. Third Series, Vol. VII., Part I. October, 1911. London: Charles Griffin and Co. Annual subscription 21*s.*, post free.—The current issue of the *Journal of Anatomy and Physiology* contains, among other contributions, some of the papers read before the Anatomical Society at its annual meeting held in Aberdeen last June. Foremost among these Aberdeen papers is the Presidential Address of Professor R. W. Reid, President of the society, entitled "Remarks on Fifteen Years of Anthropometric Work in the University of Aberdeen." Professor Reid deals with the schedule of data in use in the anatomical department at Aberdeen, discusses the methods of taking and recording the various measurements and observations, and sums up the comparative value of each item so obtained. No less than 824 students have been examined on the lines laid down in the schedule, and all the data concerning each one are recorded twice, once during the first year of medical study and again on the completion of the fifth year. The comparison of the two series of figures brings out many points of interest concerning the changes taking place in the body between the nineteenth and twenty-fourth years of life. The collection of this vast amount of anthropometric information about the physical type and the growth of the Aberdeen medical student is obviously an extremely useful work, and at the same time a very laborious one. We note that Professor Reid is a strong advocate for simplification and for uniformity of data collected; and it is apparent that by a wider use of some simplified schedule in schools throughout the country a mass of information of the utmost anthropological importance might be obtained. The schedules employed at Aberdeen are reproduced with the paper, and they would form an excellent basis for the foundation of a system capable of extremely useful extension. Professor A. M. Paterson, in a short paper on the Subscapularis Muscle, describes the normal form of the muscle and its variations brought about by reduction or multiplication of its septal divisions. Professor Arthur Keith and Mr. Francis H. S. Knowles give a description of teeth of Palæolithic man from Jersey. These teeth were found, along with bones of the woolly rhinoceros and implements assigned to the Mousterien period, in a cave situated in the cliff at St. Brelade's Bay on the south coast of Jersey. Nine teeth were first discovered, and their description occupies the bulk of the paper; subsequently four more of the same set were found and their characters are discussed in an additional note. From a comparison of the features of these Jersey teeth with those of the well-known Heidelberg mandible and the Gibraltar cranium, the authors conclude that their former owner—Homo breladensis—was "an early representative of the Neanderthal race." Two papers by Professor C. J. Patten deal with some anomalies of the cranial bones in a young orang-outang and a chimpanzee. The remnants of the retractor bulbi muscle in man are described and very clearly figured by Mr. S. E. Whitnall, who follows the evolutionary history of the muscle and instances the very few cases in which its human occurrence has been recorded. Dr. F. Wood Jones deals with some markings on the cervical vertebræ which are caused by contact with cervical nerve-trunks and serve to distinguish the various members of the cervical series of vertebræ from one another. A paper by Dr. J. Cameron is entitled "Further Researches on the Rods and Cones of Vertebrate Retinæ." Dr. Sydney J. Cole, in a paper entitled "Remarks on Some Points in the Fissuration of the Cerebrum," deals with three Chinese brains recently acquired by the Museum of the Royal College of Surgeons of England. Charts and descriptions of the convolutions and fissures of these brains are given, and the author, in his concluding remarks, discusses the nature of the arcuate and lunate sulci. Professor A. C. Geddes has a very useful practical article on the Technical Difficulties of Wax-plate Reconstruction. The fact that many workers in reconstruction processes have not attempted to solve—or have not even experienced—some of these difficulties, does not make the difficulties any less real, but certainly implies that among the present flood of reconstruction literature there must be much of which the conclusions are probably based on the study of very distorted material. Professor Geddes has done good service by indicating the devices employed in the department under his charge for overcoming several sources of error which render uncontrolled work of such very doubtful value. Dr. W. L. H. Duckworth contributes a Report on a Skull from British East Africa, and also an article on the Natural Repair of Fractures as seen in the Skeletons of Anthropoid Apes. Dr. D. G. Reid describes a case of Multiple Heart Anomalies. The most striking departures from the normal are that four presumably congenital perforations existed on the interauricular septum, and that the pulmonary valve had four cusps. The specimen has the distinction that it came from a man who had reached his seventy-second year. Mr. A. B. Appleton, in a paper entitled "A Case of Abnormal Distribution of the Nervus Musculo-Cutaneus, gives a full description of a dissection in which an absent radial nerve was replaced, not by the ulnar, but by the musculo-cutaneus. A good figure of the anomaly is given.

The Yellow Fever Bulletin. Nos. 3, 4, and 5 (for July, August, and September, 1911).—These numbers maintain the reputation of this new journal. A special feature in each of the three numbers is an original article by the editor, Dr. Harold Seidelin, the subjects of which he treats being (1) some differential leucocyte counts in yellow fever; (2) the diagnosis of yellow fever cases; and (3) the post-mortem diagnosis of yellow fever; in each of these he gives his readers the benefit of his own ripe and varied practical experience of the disease. In addition to these original articles each number contains one or more editorials on points of interest in connexion with yellow fever, such as quarantine measures, the microscopic examination of blood and tissues from yellow fever cases, and yellow fever in West Africa. There are also each month reviews of recently published books, pamphlets, or papers relating to the disease, and each number contains also a bibliography

This bulletin appears to us to be fulfilling a very useful function, and in our opinion it cannot fail to prove of service to all those who in their professional capacity are likely to be brought into relation with actual yellow fever or with suspected cases.

The Philippine Journal of Science. Vol. VI., No. 3, June, 1911.—This number is of more than usual interest at the present moment since it contains three articles dealing with the still vexed question of the etiology of beri-beri. The first of the three is a Study of the Influence of Rice Diet and of Inanition on the Production of Multiple Neuritis of Fowls and the Bearing thereof on the Etiology of Beri-beri, and is the joint work of Major Weston P. Chamberlain, Major Horace D. Bloombergh, and Captain Edwin D. Kilbourne of the Medical Corps of the United States Army, members of the Army Board for the study of tropical diseases as they exist in the Philippine Islands. The paper is illustrated by four plates and five charts. The authors found experimentally that fowls developed multiple neuritis when fed exclusively on "polished" rice; and fowls kept entirely without food of any kind, save water, also developed polyneuritis in some cases. The signs, symptoms, and nerve appearances are identical in neuritis produced by inanition and in that caused by an exclusive dietary of polished rice. In neuritis-producing rice and in beri-beri-producing dietaries both phosphorus and potassium are markedly reduced in amount. As an indicator of the beri-beri producing power of a given rice the reduction in the potassium content is probably as reliable as the reduction in the phosphorus content. In the second of these articles Dr. Victor G. Heiser, Director of Health in the Philippine Islands, gives his practical experiences with beri-beri and unpolished rice; he furnishes also an account of the means proposed to be taken by the Legislature to secure that only the unpolished variety shall be used when rice is the staple article of diet. The third article is by Major Chamberlain and Captain Edward B. Vedder, of the Medical Corps of the United States Army, entitled, "A Contribution to the Etiology of Beri-beri," giving details of a series of experiments on fowls, repeating in part the work of Fraser and Stanton, which showed that 85 per cent. of the phosphorus in rice polishings is negligible in the prevention of polyneuritis gallinarum. They conclude that this malady in fowls is not prevented by adding to the diet of polished rice any of the following substances—viz.: potassium phosphate or potassium citrate, carbonate or chloride, or magnesium phosphate, phytin, phosphoric acid, or phosphoric acid with potassium chloride. The neuritis-preventing substance in rice-polishings is soluble in cold water and in cold alcohol, and an extract made in this way was found, on analysis, to contain the following percentages, viz.:—total solids, 1·34; ash, 0·03; phosphorus pentoxide, 0·00165; nitrogen, 0·0406; and sucrose, 0·88. Polyneuritis gallinarum is not, in the opinion of these investigators, caused by lack of phosphorus compounds in the rice. The neuritis-preventing substance in rice-polishings is capable of dialysis through a parchment membrane, and this excludes all colloids from consideration. The authors realise that their conclusions are based on a small series of experiments, but further researches are being made to confirm the above observations and also to determine the effect on fowls of the remaining untried substances contained in the extract mentioned above, including the sucrose.

CORRECTION.—Mr. T. A. Welton, whose work, entitled "England's Recent Progress," was reviewed in THE LANCET of Oct. 21st, 1911, points out that in our review the word "married" on p. 1140, line 19 from the top, does not accord with the argument in the context. The author has put his finger on a slip in our review which we regret.

New Inventions.

ELECTRICAL OSMOSIS FOR DENTAL ANÆSTHESIA.

Dr. A. B. Tugman, dental surgeon to the Lisbon Medical College, and dentist to the British and Colonial Hospital and School of Tropical Medicine, Lisbon, has devised an apparatus for the anæsthetisation of the tissues of the gum and alveolus without the employment of strong solutions of cocaine, and we have had an opportunity of inspecting it. Cataphoresis—that is, the introduction of a drug by means of an electric current—has hardly, we believe, been employed hitherto for the anæsthetisation of the gum, and Dr. Tugman has modified the method of cataphoresis as used in other parts of the body in order to obtain a more localised effect of the drug and to

Showing the negative pole for applying to the sides of the head, and the syringe employed.

be able to use a current of harmless voltage. The negative pole is not applied to the back or hand, but it is placed on the side of the head over the position of the Gasserian ganglion. The positive pole is then attached to a dental syringe filled with the anæsthetic solution employed. This solution contains 1 per cent. of beta eucaine with adrenalin and some antiseptics; the needle of the syringe is inserted where required and the solution is injected, while at the same time the current passes, carrying into the tissues the anæsthetic. Dr. Tugman claims that the anæsthetic is carried much deeper than would otherwise be the case, and that the anæsthetic effect is much more complete, so that the operation is completely painless. The method is well based, but the question of its practical utility can only be answered by an extended trial. The apparatus is manufactured by the Dental Manufacturing Company, Limited, Alston House, Newman-street, London, W.

IN regard to the notice of the report, issued by Mr. E. Merck, which appeared in our issue last week, we are informed that the firm has received a large number of applications for copies, but as these are not yet ready, some delay in sending them out is bound to occur. Mr. Merck asks us to mention to our readers that their applications will be attended to with as little delay as possible.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 11, 1911.

The National Insurance Bill.

WE have published recently many communications which show the strong feeling of resentment that exists in the medical profession against the payment of their services upon any form of capitation fee instead of upon the principle of work done. The existence of a difference of opinion between members of the medical profession upon this vital point has been fully realised in these columns from the day that the Bill was first made public; it was one of the main things which prompted the articles that appeared in our columns week after week during the summer urging that there should be a delay in the proceedings for passing the Bill until unanimity upon this very vital point had been arrived at. This view was assisted powerfully by the liberal-minded and important letter which appeared in THE LANCET of June 17th from Sir ALFRED PEARCE GOULD, the message of that letter being to urge that the medical profession, while it had a chance, and while it was being assured on all sides that the Government only desired to come to a reasonable understanding, should declare once and for all that it would have nothing to do with contract practice. No move, however, was made by the medical profession at the time of sufficient importance to make an impression on the current of events—for our own part we were constrained to believe that the medica profession did not share our apprehensions. Despite the numerous modifications which the measure has undergone in Committee, and despite the apparent concessions to medical feeling which have been made by the Chancellor in response to the energetic work of the British Medical Association, the position is unchanged, save that the sands of time have largely run out. The difference of opinion still exists, but it has now become very late for medical men to consider whether they can take over the medical responsibility of the National Insurance Bill on the principle of payment for services done, supposing that there is, as we have been assured by many of our correspondents, a preponderance of feeling in favour of this principle.

No one appears able to say how far the British Medical Association, which is credited by many of our correspondents with being definitely committed to assist a system of capitation payment, has taken this line, either in so many words or so many deeds, for the circumstances of the negotiations between the Association and the Government have been complicated and protracted, as in all the circumstances they were bound to be. It was certainly understood at the beginning of these negotiations that the National Insurance Bill, as far as medical service was concerned, was founded upon the principle of capitation payment. We know that the Chancellor had the capitation principle in his mind, and it was consequently a reasonable deduction that when the British Medical Association, in the course of the *pourparlers*, did not specifically object to this principle, it had acquiesced in it. On the other hand, it would seem that the Local Health Committees are at liberty to make any arrangements they like with regard to the remuneration of the medical men working under the scheme, while in the six minimum requirements formulated by the British Medical Association there is no mention of contract practice or *per capita* payment. It is only stated that the remuneration is to be adequate and in accordance with the wishes of the majority of the profession in each locality. That the Association is not actually committed to any course of action in regard to the payment of the medical profession working under the scheme is borne out by the words of Mr. SMITH WHITAKER, medical secretary of the Association, at Edinburgh last week. Referring to the question of payment by capitation or for attendance, he said that it was open for the authorities under the Bill, if they thought proper, to establish a universal system of payment for attendance, but he looked forward to the Local Health Committees taking the advice of the Local Medical Committees upon the terms of employment of medical men. It is impossible not to see now that the medical profession is in an extremely uncertain position.

We are still of the opinion, expressed more than four months ago in these columns, that if the medical profession had carried opposition to the Bill to the point of insisting that there is no necessity whatever for the perpetuation of the contract system of medical attendance, a settlement of the difficulties might have been found; but even in June it seemed to us that time was lacking to enable the matter to be dealt with in a properly broad manner, and now the passage of the Bill with its medical provisions in a dangerously uncertain condition seems nigh upon us. We published recently a letter from Dr. H. B. LUARD which attracted the attention of many readers, and to this letter we affixed a note which, while pointing out for the fiftieth time the harm that had already been done to professional and scientific work by the contract system, alluded to the presumed acquiescence of the majority of the medical profession in that system. We are now assured that the majority of the medical profession are opposed to the contract system, while it is apparently not admitted that negotiations with the Chancellor have been carried on with any recognition that there must be a vast extension of this. It seems, therefore, likely that when the Local Health Committees begin their onerous duties there will be every opportunity for a series of fights between them and the medical profession. The drastic alterations made by the Chancellor in the constitution of these Committees has reduced the medical representation upon them to a ridiculous point, and under the new formation of these bodies medical benefits may be administered without regard to professional requirements.

The International Eugenic Congress.

IN our last issue we announced the fact that the First International Eugenic Congress is to be held in London in July, 1912, under the presidency of Major LEONARD DARWIN. The list of vice-presidents contains the names of men distinguished in the most varied fields of intellectual activity at home and abroad, while it is right and appropriate that the first International Conference on Eugenics should take place in England and that its president should be one who is a son of CHARLES DARWIN and a cousin of FRANCIS GALTON. The Congress will be held at the University of London, its organisation is in the hands of a strong committee of the Eugenics Education Society, and the object of the promoters is primarily to make more widely known the results of the investigations of those factors which are influential in producing racial results, either of improvement or of decay. In as far as certain information can be obtained on this matter it will become possible to discuss to what extent existing knowledge warrants legislative action; and thirdly, when agreement in any particulars is reached it will be a practical measure to organise the coöperation of existing societies and workers, for example, by the formation of an international committee. By expressing our sympathy and agreement with such a programme we are recording the views of all medical men.

In trying to form a just estimate of what is meant by eugenics and to what such study may lead, it is necessary to brush aside much that has been written by facile pens and uttered by sentimental mouths. The forced mating of men and women; the wholesale castration of those unfit to procreate; the segregation of what may be termed generically immoral persons—all these things are debated as though each of them, or some blend of them, might form a receipt for the production of a perfectly healthy race. Such debates have not been useless, because they have interested large masses of the public whose ideas in this way have been stimulated and clarified; but, alas, in their course much nonsense has been allowed to pass into currency. Eugenics is defined by its responsible exponents as "the study of agencies under social control that may improve or impair the racial qualities of future generations, either physically or mentally." This definition, which is accepted by the promoters of the forthcoming Congress, commits no student of the science to any drastic scheme of race-culture based upon the views of extremists. It implies that the immediate aim of eugenics is the gathering together of facts and the diffusion of knowledge; the evil must be laid bare and its consequences impressed upon the public mind before any scheme of constructive reform is translated into action. The resources of science must be employed upon the problem of racial decay, but biology and mathematics will avail little unless a campaign of popular instruction is organised, so that when the advisability of any public step is declared the people may be ready to support the movement. The medical profession, sooner than any other body of citizens perhaps, has realised that the tendency of civilised society, as it is now organised, protects the unfit at the expense of the fit. A process of unnatural selection threatening the very future of the human race has not actually set in, but our readers know well that in some ways the very perfection of modern medical and surgical practice has contributed to the perpetuation of inferior stock. This is no reproach to medicine, but it certainly implies an obligation upon it to bear a full share in investigating the sources of danger, and in applying whatever remedy is feasible to any mischief that is proven. Apart, therefore, from the great scientific interest of the subjects under discussion, the International Eugenic Congress deserves the most cordial support from medical men, since they, above all others, are alive to the need for coöperation between men of science and the public. In the words of the preliminary notice of the Congress: "At present the most urgent need is for *more knowledge*."

Cancer Research.

THE appearance of the Fourth Scientific Report of the Imperial Cancer Research Fund will be welcomed by all those who have at heart the discovery of the laws of malignant growth and the formation of an effective treatment founded thereon which shall remove from among us a veritable scourge of man. Laymen are as anxious as medical men to find the way of escape, but, appreciating the terrors of the disease more than the obscurities of its origin, they are naturally impatient that no panacea has yet been found. Every issue of the annual report of the Cancer Research Fund, however, has recorded some further steps in the difficult journey of cancer research, and in this volume are to be found many facts bearing directly on the subject of malignant disease which may have an important bearing on its etiology or therapy. The valuable introduction by the Director of the Laboratories, Dr. E. F. BASHFORD, summarises the knowledge which has been gained through the work carried out under the Fund; and all who read it will agree that in many places we have now exact information where before there was much of conjecture, and that the directions in which search should be made for facts to solve some of those problems which still remain are growing more easy of appreciation. It is only natural that those who fail to understand the difficulties of the problem should chafe a little at the failure to discover "a cure," but those who are able to appreciate the thoroughness with which the work already accomplished has been done will acknowledge that real advances have been made. At any rate, we know much more than we did formerly; biologists and bacteriologists, medical men and public, must have patience, and the desired goal will be reached. And perhaps at the last success may come suddenly.

In some ways the most valuable feature of this report deals with the results of operative treatment upon mice. At the present time no surer method of treatment than operation exists—indeed, no other method of treatment comes at all near it in value—so that it is of the greatest interest to know what has been the outcome of operative treatment for undoubted malignant disease carried on among a group of carefully observed animals. There are certain difficulties in operating for malignant

tumours in mice. In the mouse the mammary gland is not a closely aggregrated mass of tissue as in the human being; it is spread out over a large surface of the body, and therefore it is practically impossible to remove the whole gland as in the human subject. Further, as the tumour is relatively large compared with the size of the mouse, and there is a difficulty in covering the wound, it is necessary when removing the affected tissues to keep close to the tumour. Recurrence consequently must occur frequently, being due doubtless in the main to incomplete operations, but none the less suggestive information can be gathered from the recorded results. The great majority of the recurrences appeared within eight weeks, and therefore when mice have died within that time without recurrence the cases have been disregarded. In two-thirds of the cases in which recurrence was noted it took place before the end of the sixth week, and only isolated cases occurred after the tenth week; it is an open question whether these late recurrences were not really newly developing tumours. In 23 unoperated cases the average duration of life has been about six weeks after the tumour has come under observation. On the other hand, of 141 cases operated on, the length of observation has averaged 15 weeks. Too much stress must not be laid upon these figures, as preservation of life has not been the main consideration. Yet they show clearly the advantages of operation in prolonging the life of the animal. A mouse seldom lives more than one hundred weeks in all, so that on an average nine weeks have been added to its life, representing an increase of nearly one-tenth of the whole span of life. This is a substantial prolongation, and affords useful evidence of the value of operation even in cases in which recurrence sets in. We have here a remarkable justification of the undisputed course that should be pursued in most forms of malignant disease—viz., that as complete a removal of the disease as is possible should be practised immediately after the establishment of the diagnosis.

The influence of heredity in the production of malignant disease is a second interesting matter in connexion with which the report furnishes material for discussion. It has only lately been possible to submit to experimental investigation the alleged facts in support of, or contradictory to, the theory that cancer is a hereditary disease. In man the length of life and the uncontrollable conditions of human mating limit greatly the facilities for collecting accurate statistics, so that the opportunities afforded by such short-lived animals as mice should prove of value. Breeding experiments with cancerous mice have been in progress in the laboratory of the Imperial Cancer Research Fund for the last five years, with the object of collecting data to determine whether an enhanced liability to cancer is transmitted from parent to offspring. There are many possibilities of error in an investigation of this nature, for it is important not to assume that an animal is of non-cancerous ancestry merely because its ancestry is not known. As malignant disease is far more common in female mice than in males, statistical studies of any value can only be made on figures obtained from observations on female mice. Two groups were made; into one were placed mice whose mother, one or both grandmothers, or all three, had been cancerous and mice whose mother and grandmothers had not suffered from malignant disease. The numbers were large enough to reduce accidental errors to small proportions, and as a result of these observations the conclusion is drawn that female mice in the ancestry of which cancer of the mammary gland has occurred not farther back than the grandmother are more liable to develop the disease spontaneously in this organ than those in whose ancestry cancer is more remote. It must be confessed that the difference is not great, but so far as these statistics go it exists. The increased liability is probably of the nature of a predisposition of one particular tissue or organ to undergo cancerous transformation, and from a clue of this sort wide-ranging truths may become evident.

Annotations.

"Ne quid nimis."

RECENT INVESTIGATIONS INTO THE ETIOLOGY OF ENDEMIC GOITRE AND CRETINISM.

THERE are few diseases which can compare with endemic goitre and cretinism as regards the number and variety of the theories put forward at one or another time to account for their origin. Many authorities at the present time hold that these two maladies are due to one and the same cause, goitre being a milder manifestation of the poison which in greater intensity gives rise to cretinism. Most of the hypotheses advanced in the past have inculpated some constituent of drinking water as the source of the mischief, and hardness of the water as the cause of goitre and cretinism has kept a foremost place for a long series of years. Nothing definite, however, could be proved, and the most that could with confidence be affirmed was that goitre (and cretinism) must be originated by "something" in the drinking water which took up the poison from the layers of the soil through which it passed. As far back as 1877 Klebs suggested that cretinism might be an infectious disease derived from the soil, and later Ewald expressed the opinion that cretinism and its "near relation" goitre might have to be reckoned among the infectious ailments, the source being some organic "miasma," in the soil of endemic localities, and conveyed to human beings by the drinking water. Of recent years the hard-water theory has had less support than formerly, opinion having turned in the direction of a specific microbe as the cause of goitre. But there are still some authorities who uphold the hard-water theory, and one of the most prominent supporters of it at the present time is Dr. Répin, of the Pasteur Institute, Paris, who has this year published in the *Revue d'Hygiène* (Nos. 4 and 5, 1911) an able and interesting article on the subject. He insists that we cannot put aside the theory, as lime and magnesia hold a conspicuous place among the chemical constituents of goitrigenous water. He quotes also the opinion of some well-known physiologists that the thyroid gland controls the metabolism of calcium, and he suggests that it is possible that this organ acts "by modifying the concentration of the calcium-ion and the sodium-ion." Some experts, such as Professor Wilms of Basle, assert that the *materies morbi* is not a "miasma," but an organic soluble substance which can pass through a Berkefeld filter. A large amount of original investigation of goitre has been done in recent years by Captain R. McCarrison, I.M.S., Agency Surgeon at Gilgit in the North-West of the State of Kashmir, who has availed himself of the opportunities afforded by a prolonged

sojourn in a goitriferous region to make a study of the disease. Since 1906 he has published papers, reporting his progress, in THE LANCET and in other medical journals, as well as in the Proceedings of the Royal Society. In the *Indian Medical Gazette* of July last he contributes a *résumé* of his researches on goitre in Gilgit, and in the *Annals of Tropical Medicine and Parasitology*, Vol. V., No. 2, August, 1911, he supplies a communication on the transmission of goitre from man to animals. One of the main obstacles to advancement of the etiology of goitre in the past was the lack of precise knowledge as to the functions of the thyroid gland. Captain McCarrison believes that one of its chief functions is to protect the body from the many toxic substances which find their way into the blood-stream from the intestinal tract, the thyroid undergoing hypertrophy in certain circumstances to meet the demands made upon it. He regards goitre as an infectious disease, the seat of which is in the alimentary canal, the enlargement of the thyroid being the dominant symptom. This enlargement begins as a hyperæmia or simple hypertrophy due to increased functional activity of the organ brought about by the presence of toxic substances in the blood-stream. Goitre he regards as a disease associated with contaminated water-supplies, the toxic agent being in the soil from which it is washed by the rainfall into unprotected wells or streams, or blown with dust into uncovered tanks or other sources of drinking water. The disease may also be induced by habitual consumption of raw vegetables grown in infected soil. The specific agent can be killed by boiling the water, or it can be removed by passing the water through a Berkefeld filter. Captain McCarrison produced enlargement of the thyroid in himself and a number of other persons by daily consuming some of the residue taken from the filter; but when the residue was boiled it failed to have any effect upon other persons to whom it was administered. As has been said, he believes that the specific organism is located in the intestines, and the administration of intestinal antiseptics, he says, has cured incipient goitres, as also have thyroid extract and the bacillus bulgaricus. Experiments were carried out at Gilgit to transmit the disease from man to animals: 12 young, non-pregnant goats brought from a healthy district were supplied with water purposely contaminated by sufferers from goitre. At the time Captain McCarrison made his preliminary report 5 of the goats had developed enlarged thyroid, while 12 goats kept under precisely similar conditions, save that their drinking water was pure, remained unaffected. We believe that a prize of 1500 francs was founded in the Academy of Medicine, Paris, some years ago by the late Dr. St. Lager, to be awarded to the investigator who succeeded in producing enlargement of the thyroid gland in animals "by the administration of substances extracted from goitrigenous water, or from the soil of goitriferous districts," conditionally upon successful repetition of the results by a committee of experts appointed by the Academy of Medicine. We believe that this prize has never been awarded, but it appears to us not unlikely that Captain McCarrison may soon be in a position, if he wishes, to qualify as a candidate for the prize. In Captain McCarrison's opinion, contamination of sources of water-supply in goitriferous districts is of far greater importance in the causation of goitre than the nature of the geological strata through which the water passes. It has to be admitted that the specific organism has not yet been isolated and identified, but the evidence collected in Gilgit and elsewhere seems to point to the existence of such a microbe. A series of investigations into endemic cretinism in Styria have lately been made by Dr. Adolf Kutschera of Innsbruck, an eminent member of the Austrian Sanitary Service. His report was published in a supplement to the *Oesterreichisches Sanitätswesen* in February of the present year. He regards goitre and cretinism as due to a "filth infection," both maladies occurring most frequently in dirty and insanitary houses. He believes that the infection attaches itself to the interiors of these houses, and particularly to clothing and bedding. Cretinism, in Dr. Kutschera's opinion, is spread largely by personal contact, the danger being particularly great when an adult cretin lives in close relation with young persons, and especially infants. Even domestic animals may, he says, in this way contract the disease. He relates an instance where two young puppies lived with a family in a dirty house; one animal was accustomed to sleep on the bed occupied by a cretin; this animal became affected, and Dr. Kutschera in his published report gives photographs of this cretinous puppy. The other puppy which slept elsewhere remained normal. The danger of allowing cretins to live in the overcrowded cottages of Styrian peasants is pointed out, and the compulsory notification with subsequent segregation of all cretins in special institutions is strongly urged. This course, we fear, is hardly likely to be adopted owing to its cost. In 1906 (for which year the figures are available) there were 17,500 cretins in Austria, only 391 of whom were being treated in institutions, so that to provide suitable accommodation for more than 17,000 others would entail a considerable outlay. It is perhaps too soon to say that the true etiology of endemic goitre and cretinism has been established, but it may at least be asserted that considerable advances have recently been made, and that with a continuation of the investigations now in hand we may hope to see before long a final solution of what has hitherto been a most difficult and puzzling problem.

TIN ROT.

CERTAIN metallic elements have their sicknesses, but perhaps the tin plague is the most remarkable. If tin catches cold it will decay, it will lose its lustre, and finally crumble to a grey powder. The change is not a chemical one, for the grey powder is still tin, and it can be brought back by careful warming to its original healthy condition. Apparently, when the tin is very pure it is more susceptible to cold and consequent decay. In fact, it may be made proof against the disease by alloying it with other metals. The disease is a source of considerable annoyance and disappointment to the collectors of coins who possess valuable tin specimens in their cabinets. This curious failing of tin may possibly have led to the use of the word "tin" as a term of reproach, as in such expressions as "a tin-pot institution," or "a tin soldier." Even tin buttons have been known to crumble in this way, and organ-pipes made of tin have been found to decay after a severe winter. Tin rot, to keep up the analogy of disease, is even infectious, for decaying tin in contact with healthy lustrous tin soon spoils it and reduces it to its own unhealthy state. If tin is to be protected effectually against the ravages of cold it should be kept above 18° C. The best remedy appears to be, however, to alloy it with another metal, notably lead. There are many mysterious things about the inanimate, and the illness of certain metallic elements forms one of them. The energetic colloidal form of platinum can be "poisoned" or rendered inactive by prussic acid or corrosive sublimate; mercury gets "sick" in contact with other metals; glass gets "fatigued" under electric stress, so that it will no longer transmit certain rays until it has had a few days' rest; silver "spits" just as it changes from the molten to the solid state. In certain instances the "illnesses" referred to have been a serious drawback to the use of metals in industrial and domestic applications,

but fortunately the disease usually yields to treatment, based upon the diagnosis of the metallurgical chemist.

EXPERIMENTAL MEASLES IN THE MONKEY.

IN an annotation published in THE LANCET of Sept. 2nd under the above heading we referred to some observations carried out by Dr. John F. Anderson and Dr. Joseph Goldberger demonstrating the communicability of measles to monkeys by inoculation of defibrinated blood withdrawn from patients shortly after the appearance of the eruption. We have now received reprints of some further communications which are worthy of notice. In the first [1] the observers deal with the period of infectivity of the blood in measles. They have now made inoculations with the blood of six human cases taken at varying times from the onset of the disease, and they are of opinion that these results consistently indicate that the period of infectivity of the blood begins at least just before the first appearance of the exanthem, and that it continues for about 24 hours afterwards. After 24 hours the infectivity of the blood is very generally reduced and it becomes progressively less after that time. They regard these observations as explanatory of the negative results of most previous workers and of the variable effects obtained by Josias in 1898. In a second communication [2] they record some experiments which appear to demonstrate the presence of the virus of measles in the mixed buccal and nasal secretions of patients suffering from the disease. By inoculation into monkeys reactions were obtained when the secretions were collected at the time of the first appearance of the eruption and again 48 hours later. The third pamphlet [3] deals with the nature of the virus of measles. As a result of numerous experiments Dr. Goldberger and Dr. Anderson conclude that the virus in the blood of measles cases may resist desiccation for 25½ hours, that it can pass through a Berkefeld filter, that it loses its infective properties after being heated for 15 minutes at 55° C., while it may possibly retain some infective properties after 24 hours at 15° C. It appears to resist freezing for 25 hours.

"SPONGE EDUCTION."

IN the *London Hospital Gazette* for July Dr. E. Ward has described an ingenious method, which seems to have originated in America, of treating certain cases of laceration of the finger in which a bare and protruding bone, or extensive stripping of the skin with denudation of the deeper parts, seems to render amputation necessary, so that the raw surface may be covered by a flap. If amputation is not done and the finger is dressed in the usual way, either with or without preliminary treatment by baths, the ultimate result is unsatisfactory, for a stump is left which is ugly, useless, and often painful, and a secondary amputation is generally necessary. The method now described, which is termed "sponge eduction," offers an alternative which makes it possible in most cases to save the full length of the stump; frequently even to lengthen the stump, so that the finger when healed will be longer than when lacerated and ragged. The bare stump is covered with a piece of sponge ½ to ¾ in. thick and cut to fit accurately the raw surface. The sponge becomes glued to the wound, and blood-vessels and granulations grow into it from the finger end. After a few days the sponge is pulled gently away from the finger and its attachment to the granulations is thereby loosened; any little hæmorrhage is absorbed by the sponge, and the granulations left behind lengthen and grow into it again. After a shorter interval the sponge is pulled further away, and this treatment is repeated until quite a thick pad grows up following the sponge and burying the raw surface or protruding bone. When the granulations are judged to be sufficient the sponge is removed and the wound dressed, first with fomentations, later with ointment or dry dressing. The granulations are rapidly covered by skin. Sponge eduction may also be used to help to re-form the pad over a terminal phalanx when torn away. In one case the patient was able to play the piano with the pad so formed. For sponge eduction a flat Turkish sponge kept dry, but soaked in 1 in 40 carbolic solution for a short time before the operation, is used. The piece of sponge is applied after hæmorrhage has ceased or nearly ceased, and after the stump has been rendered as aseptic as possible. Outside the sponge cyanide gauze may be applied or jaconet, as the granulations grow more rapidly if kept moist. If there is difficulty in maintaining the sponge in position splints may be used. Dressing is first done on the third day, and then on every other day. The sponge is kept aseptic by dipping it in weak carbolic solution and squeezing it dry at each dressing. In an ideal case the secretions from the granulating surface are sucked up by the sponge and the wound remains fairly dry. Sometimes matting of the layer of the sponge near the finger prevents this draining, and pus, pent up by adhesion of the sponge to the edges of the wound, is found. The matted part of the sponge may be cut away and the sponge re-applied or a new piece of sponge may be applied. If this fails a satisfactory growth of granulations may still occur in the moist discharge under the matted sponge. The method cannot be applied straight away in the case of a dirty, lacerated wound, but can be applied after the stump is sufficiently cleansed by baths. As a rule, the stumps left after healing are painless. Dr. Ward suggests other possibilities for this method. It can be applied to any wound in which exuberant granulations are needed. A cavity in bone after scraping out a tuberculous focus may be filled by granulations so "educed." It may be applied to fill the cavity left after mastoid operations. Ulcers of the leg adherent to bone may be scraped and granulations educed. The scar when covered with skin and epithelium will no longer be adherent to the bone.

PREHISTORIC SOCIETY OF EAST ANGLIA.

THIS society was founded in 1908, and passed its first two years of existence under the fostering care of Dr. W. Allen Sturge as president, whose presidential address at the foundation meeting is included in the Proceedings. The Proceedings for 1908–09 [1] contain two revolutionary papers, one by Mr. J. Reid Moir, on the Flint Implements of Sub-Crag Man, and one by Dr. Sturge, on the Chronology of the Stone Age. Mr. Moir describes some stone implements found by him near Ipswich, which he classes as "prepalæoliths," that is to say, as representing a stage of culture midway between the eoliths proper and the river drift palæoliths. The report of a special committee on these implements bears out his contention in the main. The finding of these definitely well-worked flints, which are far in advance of the Kentian eoliths in their true stratigraphical position below crag, proves, he asserts, that since their makers lived the Newbournian, Butleyan, Norwich, and Weybournian Crags, the Chillesford Crag and Sand, the Cromer Beds, and the Glacial Series have all been laid down, thus giving to man an antiquity in these islands never before realised. Dr. Sturge, by a lengthy and closely reasoned study of Icklingham, in Suffolk, probably one of the richest places in the world for human flint work of the Neolithic age, is led to the conclusion that since Neolithic

[3] Ibid., Sept. 16th, 1911, pp. 971–972.

[1] Proceedings of the Prehistoric Society of East Anglia for 1908–09 and 1909–10, vol. i., part 1. London: H. K. Lewis, 1911. Pp. 121. Price 3*s*. 6*d*. (postage 3*d*.).

man came to Britain there has been an ice age—not continuous, but divided up into subperiods of glaciation, separated from one another by periods during which ice was absent, and that this alternation recurred several times, five at least, and probably six. He gives weighty reasons for inferring that the periods of recurrent glaciation came to an end some scores of thousands of years ago, and that they were separated from one another by lengths of time which have to be measured by a unit of 10,000, rather than of 1000, years. The conclusion of the whole matter is that Neolithic man goes back to some period between 200,000 and 300,000 years ago, and it would seem that we have not even then reached the beginning of the period. Drift man was flourishing from 1,000,000 years ago to about 700,000 years. Between the end of the Drift and the beginning of the Neolithic we have the great "Cave" periods, which would thus seem to have occupied anything from 200,000 to 400,000 years. Behind Drift men are vast ages of which we are only beginning to get the first glimpses. But it seems evident, says Dr. Sturge, that in spite of the general opinion man was already on the earth in early Pliocene times, and it will not be a matter for surprise if proofs are ultimately brought forward that the genus homo goes back even further than that. The Proceedings close with a paper by Lieutenant-Colonel W. Underwood on Animistic Forms in Certain Flints, showing Human Work.

TRANSIENT APHASIA AND PARALYSES IN STATES OF HIGH BLOOD PRESSURE AND ARTERIO-SCLEROSIS.

IN the *Canadian Medical Association Journal* for October Sir William Osler has discussed a condition which, though not uncommon, has received little attention from medical writers—transient aphasia and paralyses in states of high blood pressure and arterio-sclerosis. The subject was brought before the Association of American Physicians in 1891 by Dr. George Peabody, who seems to have been the first to offer a reasonable explanation of its pathology. In one of his cases, a man, aged 56 years, with well-marked arterio-sclerosis, had an attack of transient hemiplegia without loss of consciousness. Then in the course of ten days he had four or five attacks of aphasia with incomplete right hemiplegia. He died in a severe attack in which he had complete right hemiplegia with unconsciousness. Extensive arterio-sclerosis was found in the cerebral vessels, but there were no local lesions, no œdematous areas, and no foci of hæmorrhage or softening. Dr. Peabody suggested that in addition to the narrowing from arterio-sclerosis there is spasmodic contraction of the middle cerebral artery or its branches which is sufficient to cut off the blood-supply of the parts to which it is distributed; that this occurred several times, causing temporary ischæmia of important brain centres; and that in the final attack it lasted long enough to be fatal, but that it was not complete enough or of sufficiently long duration to cause softening. He urged that as spasm can be seen in the retinal vessels in cases of transient loss of vision the same occurred in local vascular areas of the brain. Dr. Peabody's important and original paper received recognition only in Sir William Osler's text-book, when the first edition was published in 1892. Since then Sir William Osler has seen a score or more cases which he divides into three categories: 1. Healthy individuals with high blood pressure, but without signs of arterial disease. In one case an active man, aged 43 years, who worked hard and was given to dissipation, returned to his hotel, rang the bell, and found that he could not speak. He was perfectly conscious and much disturbed, especially when he found he could not write. He was a little dazed and could not tell the time. He became emotional and a medical man who was summoned found him crying and still unable to speak. In a few hours he could say a few words, but incoherently. On the next day he could talk, but not quite freely. Within three or four days he completely recovered. The blood pressure was 212 millimetres. The radial and temporal arteries could be rolled under the fingers with the blood flowing, but when emptied were not palpable. There was no evidence of enlargement of the heart; the second aortic sound was ringing. 2. In the second category, which includes the majority of the cases, there is well-marked arterio-sclerosis. The cerebral attacks come on without warning, sometimes as the signal symptom. 3. In the third category there is advanced arterio-sclerosis with cerebral changes, manifested by progressive mental and muscular weakness. All possible types of transient seizures, including convulsions, may occur. The symptoms of these transient attacks are extraordinarily varied, but tend in individual cases to repeat themselves. Transient aphasia is one of the most common. Hemianopia may be present. Sensory disturbances rarely occur alone, but one patient had day-long attacks of numbness of the face and right hand with loss of the finer movements of the fingers. Paræsthesiæ may exist with aphasia. Motor paralysis is the most common symptom and may take the form of hemiplegia, or only the face and hand or arm may be involved. The paralysis is rarely complete. In one case brief paraplegia occurred. Confusion of thought often occurs, and emotional disturbances, which are very natural under the circumstances, are common.

THE EXPORT OF CHINESE PORK TO ENGLAND.[1]

WHEN it became known last year that Chinese pork was being imported into London some public anxiety was manifested, as it was declared by people who had lived in the East that in China the pig was a public scavenger, and that Chinese pork would be sure to spread disease—parasitic, tuberculous, and other—in those who ate it. Advantage was taken accordingly by the Local Government Board of Dr. Reginald Farrar's presence in the East this spring in connexion with the International Commission on Plague to have the matter investigated. He was instructed to inquire into the export of Chinese pork, and with this object in view has travelled through the Yangtse Valley, Manchuria, and Siberia, and after careful examination he has drawn up a most reassuring report. The export of Chinese pork is very considerable and is growing. One firm at Hankow shipped last year a weekly average of 30 tons of pork (some 600 pigs). The figures are, in a sense, satisfactory, for it is obvious that a trade of this magnitude must be managed throughout on a large scale, its requirements being too great to be supplied casually from the stray pigs wandering about the streets and lanes of towns. As a matter of fact, it appears that these stray pigs are not exported, but are consumed locally. Those for export are of better breeds and are grown on farms under conditions quite as good as those we know in England. They are generally fed on rice, but the well-reputed Yun-nan pigs in the south also get maize, and in Manchuria they have soya-bean or bean curd too. In Siberia they are given bran and oats boiled with butter-milk. As the outcome of his inquiries Dr. Farrar tells us that the Chinese pig is conspicuously free from disease—trichinosis is unknown in the south, cysticercus cellulosæ and tubercle are very rare. Inspection of carcasses is carried out everywhere

[1] Report to the Local Government Board by Dr. Reginald A. Farrar on Inquiries in China and Siberia Respecting Pork and Bacon Exported to England. [Food Reports No. 16.] Pp. 15. Price 4d. Stationery Office: Wymans, London, &c.

and by experts. The most complete inspection is reported from Siberia, where a pig is not killed if its temperature (taken in the rectum) is notably above or below normal. After slaughter the carcass and "pluck" are inspected, the glands being cut into, and the muscular tissue is microscopically examined for trichina, which is sometimes though rarely found in the north. It is probably important to notice that the highest prevalence of tubercle is reported from that district whose head inspector prides himself that no carcass he has passed has ever yet been rejected in England. Inspection again in England is very thorough, and in accordance with the report of the Royal Commission on Tuberculosis the smallest evidence of tubercle suffices to condemn the whole carcass. The necessity for this drastic procedure does not seem to obtain in China, so there is need for careful inspection in the home ports, but if it has once passed our inspectors there is no need for further prejudice against it. In an interesting "aside" Dr. Farrar tells us that the Hunanese pig is taught, by a bamboo, to keep the board floor of his sty dry and clean, and soon learns to leave all his excreta in one corner of the pen. Might not some such discipline be attempted with our house dogs in cities? Are they more silly than pigs? Could they not be taught to respect footpaths and side walks, or have we not yet treated our pets intelligently for a sufficient space of time? The complicated characters of Chinese writing are ideographs, and the character that suggests to a Chinaman the idea of "home" is, Dr. Farrar tells us, an outline picture of a pig under a roof. This suggests that the pig became domesticated there countless ages ago. Dr. Farrar is to be congratulated on his interesting work.

VARICOSE VEINS AND A SAPHENO-FEMORAL ANASTOMOSIS.

THE number of operations which have recently been devised for the treatment of varicose veins shows how unsatisfactory the present operative treatment of this condition is. Even total extirpation of varicose veins is sometimes followed by relapse. Trendelenburg's operation is unsatisfactory for the same reason. Elephantiasis has so often followed Wenzel's circular division of the veins that his operation has already been permanently shelved; and the spiral method of dividing the veins as advocated by Rindfleisch has not yet emerged from its experimental stage. E. Hesse and W. Schaak have recently (in the *Archiv für Klinische Chirurgie*) published their observations on the treatment of varicose veins by a sapheno-femoral anastomosis as advocated by Delbet in 1906. This operation was evolved from the observation that the stagnation of blood in the saphenous area is due to the total or partial absence of valves in the upper part of the saphenous and femoral veins. Assuming that the femoral vein is well supplied with valves immediately below its juncture with the saphenous vein, it was argued that normal circulation would be re-established if the juncture of the saphenous with the femoral vein were made at a lower level by an "end-to-side" anastomosis. By this operation a segment of vein with efficient valves would be inserted between the large abdominal and femoral veins on the one hand, and the veins of the saphenous area on the other. The question naturally arose, What is the exact valvular distribution in this segment of vein? The writers therefore examined 100 dead bodies in order to answer this question, and their findings may thus be summarised: 1. The femoral vein possesses usually one, and occasionally two, pairs of valves above its juncture with the saphenous vein, but in 23 per cent. there are no such valves present. 2. Below this point the femoral vein has at least two pairs of valves; usually there are more, and there is an interval of 3 to 4 centimetres between each pair. Occasionally the highest pair is as much as 7 to 10 centimetres below the opening of the saphenous vein. 3. The saphenous vein usually has a pair of valves close to its opening, and there are usually several pairs of valves lower down. 4. There may be several accessory saphenous veins in addition to the main vessel. Finally, the writers conclude that the anastomosis to be effective must be made at least 10 centimetres below the original juncture of the saphenous with the femoral vein. The operation is performed without previous emptying of the veins. A 12 to 15 centimetre long incision is made over the femoral vessels in Scarpa's triangle, and a considerable length of the saphenous vein is loosened from the surrounding structures so that there shall be no tension on this vessel after the anastomosis has been effected. All its branches and the accessory saphenous veins having been ligatured the saphenous vein is tied close to its opening. It is now clamped and divided obliquely. After the femoral vein has been separated from its companion artery for a distance of 5 to 7 centimetres, it is compressed by clamps between which an opening is made in it corresponding in size to the circumference of the saphenous vein. The saphenous vein is now implanted into this opening by an "end-to-side" anastomosis, the same procedure being adopted as in an intestinal "end-to-side" anastomosis. When the last suture has been tied the upper of the two clamps compressing the femoral vein is first removed, then the lower clamp, and finally the clamp compressing the saphenous vein is removed. If hæmorrhage occurs it is stopped either by pressure or by additional sutures. The sartorius and adductor muscles are drawn together over the anastomosis and united by a couple of sutures. The bandages are retained for two to three weeks, and the patient is usually kept in bed two to four weeks more. This operation has been successfully performed by Delbet 25 times and by the writers 23 times, but one of their patients died from an acute infection 26 days after the operation. No doubt this is a somewhat heroic operation which requires considerable technical skill and involves risks of sepsis and embolism from air or thrombi; but the troubles which may arise from varicose veins often require drastic measures. The operation leads to the disappearance of varicose ulcers. The dilatation also of the veins ceases and the troublesome subjective conditions from which the patient has suffered also disappear. The most suitable cases are those in which the patients are otherwise healthy, the varicosity of their veins being due to valvular incompetence only. The operation is obviously impracticable where there is thrombosis of the saphenous vein.

MEDICAL EDUCATION IN GERMANY.

IN another part of this issue we print in full a most interesting and important Memorandum on Medical Education submitted to the Royal Commission on University Education in London by Professor Friedrich von Müller, of Munich. Professor von Müller makes a strong point of the fact that since the Middle Ages the German medical student has always been a member of a university, and that medical education in Germany, like all other branches of university training, is founded on the principle of absolute freedom of learning. He shows how the German system depends to a considerable degree upon the recognition by the State of its duties in the control and support of medical education. Prussia, for instance, contributes in maintenance and salaries the sum of £95 per annum towards the education of each of its 5365 medical students, and this is regarded as money spent by the community upon the prevention of disease. Professor von

Müller describes the relations between the State, the hospitals, and the medical schools in Germany, and with reference to national insurance against sickness he prophesies that if the present British scheme passes into law we shall be compelled to build new hospitals for those insured persons who cannot afford proper treatment at home. Describing in detail the curriculum of the German medical student, he draws an interesting contrast between the methods of clinical instruction in England and in his own country. Although every German medical student is a university man, each on qualifying does not obtain a university degree, which is strictly reserved as an academic distinction. The final examination for the licence to practise is conducted under the control of the Empire. The teacher is usually the examiner, and the successful candidate has to devote a further year to supervised hospital work before he is allowed to practise. The author is particularly instructive in his remarks on the fundamental difference which should exist between the licence and the degree; on the necessity for reforming methods of instruction rather than methods of examination; on the essential qualifications of the teacher; and on the importance of throwing open all professorships, clinical as well as scientific, to all comers without favour. He concludes with a powerful argument for adequate and even generous expenditure upon medical education, so that present plans for reform may be broad enough to allow for future expansion to meet the increasing demands of science. Professor von Müller's Memorandum deserves careful attention. His views will not all be accepted, but even those which are most opposed to English ideas are interesting and suggestive, and in no way detract from the value of his evidence or the force of many of his contentions.

THE DEATH OF SIR SAMUEL WILKS.

WE regret to announce the death on the morning of Nov. 8th, in his eighty-eighth year, of Sir Samuel Wilks, Bart., M.D., F.R.S., senior consulting physician to Guy's Hospital and late Physician-extraordinary to the Queen. Sir Samuel Wilks was the *doyen* of the Royal College of Physicians of London, of which he became a Fellow 55 years ago, and of which he was President from 1896 to 1898. We shall publish a full obituary notice in our next issue.

Dr. Harvey W. Wiley, head of the Bureau of Chemistry in the United States Department of Agriculture, has been invited by the council of the Pure Food and Health Society of Great Britain to preside at the forthcoming congress of the society, to be held in March next. To Dr. Wiley is mainly due the passage, and still more the successful enforcement, of the United States Pure Food and Drugs Law. Naturally, he has aroused considerable enmity through his activity, but the good sense of the American people at large has sustained him, and he has recently emerged victorious from a legal onslaught by those who have resented interference with their "legitimate business."

Dr. F. W. Mott will introduce a discussion on the Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System at a meeting of the Medical Society of London, on Monday next, at 8.30 P.M. The following have promised to take part in the discussion: Sir David Ferrier, F.R.S., Sir Victor Horsley, F.R.S., Dr. G. H. Savage, Dr. Risien Russell, Dr. T. B. Hyslop, Major H. C. French, R.A.M.C., Dr. Wilfred Harris, Dr. E. Farquhar Buzzard, and Mr. Alexander Fleming. The discussion will be continued on Monday, Nov. 20th, at 8.30 P.M.

AN extraordinary general meeting of the governors of Epsom College will be held at the office, 37, Soho-square, London, W., on Wednesday next, Nov. 15th, at 4 o'clock, when it will be proposed that alterations be made in the by-laws of the College. Governors wishing for information as to these alterations can obtain full particulars on application to the secretary at the office of the College.

WE regret to record the death from pneumonia on Nov. 1st of Dr. John Alfred Coutts, physician to the East London Hospital for Children, and well known as an authority on pædiatrics.

THE Nobel Prize for Chemistry has been awarded this year by the Swedish Academy of Science to Madame Marie Curie. The Nobel Prize for Physics has been awarded to Professor Wilhelm Wien, of Würzburg.

MEMORANDUM ON MEDICAL EDUCATION

SUBMITTED TO THE

ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

BY FRIEDRICH VON MÜLLER, M.D., LL.D.,
PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF MUNICH.

IT is impossible for me to attempt to give you advice with regard to the reform of medical education in London. I really know too little about the English medical schools of to-day, because it is many years since I visited the London hospitals, and during the last 20 years not only the science of medicine, but also the English medical schools, have made important progress.

The difference between English and German medical education is founded on their historical development, and we understand it only by the study of their history. Historical development is one of the most important factors in culture, and we never realise its importance so clearly as in the case of those younger countries where no historical development exists. But the burden of a noble past may sometimes become a hindrance to salutary reform which appears indeed like sacrilege.

Medicine and the University.

In England the instruction of the apprentices of medicine was always entrusted to the profession and the hospitals. The training was purely professional and practical as in the case of the trades. This system gave to English medicine its strength because it developed in the young beginner the faculty of strict observation, which is one of the great prerogatives of English medicine. In Germany since the Middle Ages medicine has always formed part of the university curriculum. Instruction in medicine was in former times almost entirely theoretical and historical, founded on the Latin classical literature and in closest connexion with philosophy, and even with theology. The darkest periods of decay in German medicine were those in which philosophical speculation and theological mysticism obtained a preponderant influence over medical problems.

But, on the other hand, this connexion between medical education and the University has proved beneficial because it admitted of a broader basis, a closer community with other sciences, and because it gave, and still gives, to the physician his social and intellectual position among the learned men of the nation. This is the reason why we shall never give up University education for the medical practitioner. The student who wishes to enter the medical faculty must have come through the same schools, and passed the same examinations in Latin and Greek, or in English, French, and Mathematics, as the students who intend to become lawyers, philologists, clergymen, or natural scientists. The preliminary conditions of admission to the university are the same for all students.

Freedom of the German Student.

The German medical student lives during his whole university career among the other students of the university. He has his friends, his sports, his duels among them, and therefore he is for the rest of his life connected

with the representatives of the other scientific vocations. University education in Germany is founded upon the principle of absolute freedom of learning, and this is just as true of the medical faculty as of any other. The student is not bound to follow a prescribed course of study. He is allowed to go his own way and to select his teachers and lectures himself, and nobody cares whether he is present at every lecture or whether he is idle. Only a few lectures, laboratory work, and clinics are obligatory. Too much tutelage and prescription are of no good in the education of the adult. This system of absolute liberty is of great importance for the teacher because he is always sure that his pupils come spontaneously to his lectures and not by compulsion.

The student is not bound to one university alone, he is free to wander to others, and the majority pursue the course of their studies in more than one university, like the wandering students of past centuries. We approve of this because it widens the intellectual horizon and induces a mental attitude of educated criticism. This system of absolute liberty has its dangers. Many weak and unprincipled characters are ruined by the total absence of control and neglect their studies. But the strong are allowed to develop their faculties in accordance with their own ideals. During his first and second year the medical student attends lectures and does laboratory work in physics, chemistry, botany, and zoology in the philosophical faculty, and he has the opportunity of widening his views by listening to lectures on philosophical or historical subjects. His teachers and laboratories are the same as for the students of the natural sciences, and this is right, because there is no such thing as special medical physics or chemistry, but the physician requires a broad knowledge of the general sciences of physics and chemistry.

The State and the Medical Student.

Another difference between the English and German institutions arises from the very different conceptions which obtain of the obligations of the State Government. In England and America social progress is to a great extent dependent on private initiative, and the creative impulse of independent and devoted individuals has always led to the greatest benefits for the community. In Germany and France the citizen is more accustomed to be guided by the Government, and he commits the important questions of the general welfare to the care of the State. Our view is that it is the interest of the community to obtain an adequate supply of the best medical attendants. We believe that neither the profession nor the hospitals have as great an interest as the community in the education of the young physician. Therefore it is the duty of the State Government, as the representative of the community, to care for the best possible education of the young medical generation and to provide the money for this purpose. We think this conclusion is logical. If so the State Government has also the duty of selecting the best teachers and of paying them adequately, so that they may be able to devote their whole time, or at least the greater part of it, to fulfilling their obligations as teachers. This principle applies to the clinical teacher as well as to others, for he is one of the most important in the medical faculty. It is not proper that the clinical professor should be burdened with great obligations as a teacher and at the same time compelled to support himself by private practice.

The salary of university professors in Germany is not bad. It amounts for an ordinary professorship to £200—£500 a year, and permits him to maintain a good social position. Besides the ordinary professors, who hold the principal chairs, there are extraordinary professors and junior teachers, who instruct in the auxiliary or less important subjects of medicine. They receive a salary of £100—£250 a year. The number of ordinary professors in every medical faculty is from 10 to 17. The number of the adjunct professors varies from 6 to 32. But this salary paid by the State does not form the whole income of the university professor. The student pays for every lecture or clinic a certain small sum, on the average 10*s.* to £2 for the half-year. A portion of this money is taken by the university; but the greater part goes to the professor, and this "*Collegiengeld*" forms a more or less considerable part of his income. This system is of some importance because the teacher's income depends to a great extent on the number of his students. He has therefore an interest in making his lectures as attractive as possible and in spending his time and energy for this purpose. Moreover, the State provides and maintains the buildings necessary for medical instruction and the equipment of the laboratories.

State Subsidies to Medical Education.

Every university has its large buildings for anatomy, physiology, and biological chemistry, for pathology, pharmacology, and hygiene. To keep pace with the extension of science the number and size of these institutions is constantly growing and demands enormous expenditure. I take, for example, Bavaria. It has 7,000,000 inhabitants, approximately the same as Greater London. Bavaria has three universities, and therefore three fully equipped medical faculties. The sum paid by the State for the salaries of the teachers of medicine in these three universities amounts to £19,700, or from £5000 to £8000 a year for each university. This does not include the salaries of the large number of assistants or the pensions of retired professors and the widows of deceased professors. Within the last ten years the University of Munich has got a new building for anatomy at a cost of £125,000, a new psychiatric clinic costing £100,000, a great ophthalmological clinic costing £125,000, and a new building for out-patients costing £125,000. The maintenance of these university institutions and laboratories of course involves a large annual expenditure. The sum paid for the maintenance of the different institutions for medical education, including the clinics in the three Bavarian universities, amounts to £80,000. The State Government of Bavaria was kind enough to give me these statistics and to give me permission to bring them before this Royal Commission. The other Confederate States of Germany have similar expenses for their medical faculties: Baden has two universities; Würtemberg, Saxony, Mecklenburg, Thuringia, Alsace, have each one. Prussia with its ten universities has of course much greater expenses than the other States of Germany.

At my request the State Government of Prussia has given me particulars of its expenditure on medical education. I feel greatly obliged indeed to the Prussian Ministry for Public Instruction for this information, and I am glad to be permitted to hand it over to your lordship. We learn from this evidence that Prussia spends on its ten universities for salaries for the medical teachers £116,000, for the maintenance of the medical institutes and clinics £413,200—a total of £530,000 a year. The number of students of medicine at the ten universities is 5365. Therefore the Prussian State contributes towards the education of every student of medicine £95 a year. For the building and fitting out of new medical institutes and clinics Prussia has expended within the last 25 years £2,573,400, or £102,936 a year. Every medical faculty of the 20 German universities has a medical, surgical and obstetrical, psychiatric, and ophthalmological clinic. Most of them have a clinic for dermatology and venereal diseases, for pædiatry and otology. Some of the greater ones have also clinics for orthopædics and throat diseases. Berlin and Munich have two parallel clinics, because one alone would not be sufficient for the great number of students of medicine, which in Munich exceeds 2000. In addition to the clinics there are large out-patient departments in special buildings and with their own staff of physicians and teachers. I have here a picture of the new building for out-patients in Munich erected in recent years. It contains out-patient departments for internal medicine, surgery, pædiatrics, gynæcology, otiatrics, throat diseases, dermatology, and orthopædics. The capital cost of the buildings and equipment exceeded £125,000, and its yearly maintenance costs £10,000. You see that Germany not only spends great sums for the army and navy, I say for the prevention of war, but also much money for medical purposes, and therefore for the prevention of disease.

Hospitals and Medical Schools.

The connexion between the clinical hospitals and the medical faculties is not of the same type in all universities. In some universities, such as Leipsic and Munich, the hospitals belong to the city; they are municipal, and by agreement the municipality opens its hospital entirely or partly to medical instruction. The clinical teachers are the physicians-in-chief of the city hospital, and are appointed by the city government and the university together. In Berlin the War Office of the kingdom is in possession of the Charité Hospital. The Charité was built by King Frederic

Wilhelm I. for the instruction of the surgeons of the army. In 1810 the University of Berlin was founded, and the general clinical teaching was transferred to the Charité. In some older universities the country hospitals came into connexion with the university. But with the expansion of clinical teaching it became evident that some of the older hospitals were not sufficient for the new requirements, and some municipal governments and other hospital administrations were at one time unwilling to offer increasing facilities to the medical faculties. Some of the municipalities were shortsighted enough to refuse altogether to admit students to their wards, because they feared that the patients would suffer at their inexperienced hands (and this not entirely without reason, because the patients really do suffer from too much examination).

For this reason the university—that is, the State—found itself more and more obliged to build its own university hospitals. Most of them have been built in the last 20 years, and are constructed on modern principles. It is necessary that the clinical hospitals should contain a sufficient number of beds, that they may be able to admit a sufficient selection of interesting and instructive cases, and also to cover the whole field of medicine. I think a medical clinic should have at least 120 to 150 beds. The Munich clinical hospitals have more than 1200 beds, the Leipsic clinical hospitals 1360 beds, the Charité at Berlin more than 1800 beds. But who shall pay for all these patients? The university again? No. The State pays only a comparatively small part for the admission of some specially interesting cases. The great majority of the cases are paid for by the insurance fund and by the Poor-law administration.

National Insurance and the Hospitals.

It will be well known to the Royal Commission that in Germany every workman and workwoman and all domestic servants are compulsorily insured against disease. In case of illness or accident they have the right to free treatment and admission to a hospital, and the insurance fund is obliged to pay to the hospital for every patient admitted a certain sum, averaging 3*s*. a day. This sum is almost sufficient to cover the expenses of the hospital, so that they are able to maintain their budget by the contributions from the insurance fund. The duty of caring for the destitute poor falls on the Poor-law commission of the parish, or on the municipality, and so they too are paid for. The hospital patients, therefore, are not admitted by charity, and our hospital work is therefore not so much charity work as in England. Most of our patients have a *right* to be admitted, and they cannot be discharged till they are cured, or till their time is over. This is the reason why our patients are not all willing to be examined by the students or to be made the subjects of demonstration in the theatre. The sum paid for insurance of the working-classes amounts in Germany to nearly £18,000,000 a year. Should we not characterise it as expenses paid for the prevention of social war?

England has now initiated new social laws for the insurance of the working-classes. I am sure you will soon be compelled to erect great new hospitals for those insured patients who cannot afford proper treatment at home. And it may be useful to bring those hospitals into connexion with the university teaching of medicine.

I now wish to draw your attention to some points of the existing medical education in Germany. The student enters the university at the age of 18 or 19 years. He first begins, as I told you, with physics, chemistry, biology, and other natural sciences in the classrooms and laboratories of the philosophical faculty. At the same time he receives instruction in anatomy and dissects in the anatomical institute of the medical faculty. In the second year and the first half of the third year he attends lectures in normal histology and embryology. The history of ontogenetic and phylogenetic development is proving year by year more important for the conception of pathological processes, for the anatomy of the brain, and other problems. It is therefore absolutely necessary to teach this science to the medical students. Lectures in physiology and laboratory work in experimental biology and biological chemistry complete the course of the preliminary studies. After he has passed his first examination in these subjects the student, in the second half of his third year, enters upon his professional studies through the door of general pathology and pathological anatomy in the dissecting room and microscopic laboratories of the pathological institute. At the same time he attends lectures on pharmacology, which is developing more and more into experimental pathology. In the hospital wards he takes practical instruction in the physical examination of patients, in propædeutics of surgery and midwifery, and in clinical chemistry and microscopy. He is then prepared to enter the clinic.

Clinical Teaching in England and Germany.

Our method of clinical teaching differs in one important point from yours. In English medical schools the young student is immediately brought in contact with the patient. Under strict control of the house physician he has to write the record of his patient and to follow the course of his case every day. From practical experience of a relatively small number of patients he learns how to examine and to treat them. In Germany, and especially in the larger universities, the clinical teacher shows to all his students in the theatre every day one or two selected cases which are specially adapted to illustrate the conception of the disease. The patient is examined before the whole class; the teacher explains the symptoms and discusses the general pathological questions which are connected with the case. So the student sees a great variety of diseases, and we try to give him a complete picture of the single case. Only when he has first acquired some general knowledge do we bring him into closer contact with the patient under control of the assistants. For every single patient shows such complicated possibilities that the beginner cannot understand the whole significance of the case until he has acquired a certain fund of knowledge. When the student in his fourth year has finished his hospital work in internal medicine, surgery, and midwifery, he goes to the out-patient department. Here he learns to deal with all the difficulties of his future professional life. The out-patient department should be for the advanced student the direct introduction to his practical work.

In England the student begins with the out-patient department and then enters the clinical wards. In Germany we go the reverse way. We believe it is more difficult and requires greater experience to deal with out-patients and find out quickly the essential points than to work under direction in the wards of a hospital where the cases are far better prepared and more thoroughly examined by the assistant and the head physician. During his last year the student has to attend the ophthalmological, psychiatrical, pædiatrical, and dermatological clinics, otiatrics, throat diseases, and other specialties. Lectures and laboratory work in bacteriology and hygiene and dissections of pathological cases form the conclusion.

The Final Examination and After.

After the end of his fifth year the student is allowed to go up for his final examination. But many of the students spend another half year before they do so. This examination gives the licence to practise. While the universities are under the management of the particular States, the examination is conducted under the control of the Empire, and the passing of it confers the right to practise in all parts of the Empire. The State Government controls the examination and appoints the examiners. It can appoint medical practitioners to be examiners, but as a rule the teachers—that is, the university professors—examine, and this rule has proved satisfactory. We do not find any disadvantages in this system. For the teacher it has the great advantage that he is able to find out whether his instruction has been successful, and whether his lectures were well understood by his pupils. For the student it is agreeable that he is sure not to find great discrepancies between his studies and his examinations. It is not at all obligatory that the student should pass this examination at the university at which he has studied.

After the State examination the successful candidate is not immediately permitted to enter upon his practice. He is compelled to devote a year entirely to practical hospital work under control of the hospital physicians. For this purpose not only the University hospitals but all the hospitals of Germany are open, and an average of 1200 young physicians are distributed among a large number of hospitals. In this way the more theoretical introduction of our German medical instruction is compensated by the practical work of the final year. Some of the larger city hospitals in Frankfort, Cologne, Düsseldorf, and Hamburg have established schools for post-graduates, which have been successful.

Within the last ten years the curriculum of the medical student has been extended by one half-year of university instruction and by the practical year, so that the student comes to earn his living one and a half years later than before. One could believe that this extension would keep back a great number of young men from the medical career, and would have diminished the number of medical students. Just the reverse took place. The number of medical students increased considerably. A study of so great interest like medicine, which shows such splendid scientific progress, will always attract the spirits of enthusiastic youth.

Examination is a very important thing, because it is a necessary control, not only for the students, but also for the teachers. But we should not forget that the examinations are not the principal object. They may be so in China. The range and scope of study are far more important, and it is not the province of the university to prepare for examinations but for the future life and vocation. Reform must begin with the instruction and not with the examinations. It is easy to conceive that reform often meets with more resistance from the teachers than from the students, and that it takes a much longer time and is more difficult to reform a corporation of teachers than to accustom the young generation to a reformed system.

We must distinguish sharply between the State examination, which gives the licence to practise, and the academical degree. The degree of M.D. can be conferred by the medical faculty in all German universities upon nearly the same conditions. While the State examination is especially practical and has to furnish evidence that the candidate is mature for practice, the degree of M.D. ought to indicate that the man has contributed his part to scientific work. The degree should be a scientific qualification. It is not a more rigorous second examination superimposed on the State examination which gives the degree, but the candidate must present a piece of scientific work: some experimental investigations or some clinical observations with consideration of the pertinent literature. This paper or dissertation must be approved by the faculty and must be printed.

The Qualifications of the Professor.

We have now got some idea of the course of medical study. Finally, I wish to say a few words about the teachers. Since the teachers of anatomy, biological chemistry, pathology, pharmacology, hygiene, and so on, are university professors, it is clear that their selection follows the same lines as in the case of the university professors in general. This means that in the case of a vacancy the best man available should be chosen. Only those who are actively engaged in scientific research and play their part in the promotion of science are capable of being university teachers. Since the clinical hospitals are well established institutions of the university, and because the clinical teachers are fully acknowledged university professors, they must be selected from the scientists and not from among the successful practitioners. Clinical medicine is as truly scientific as physiology, but it is not so much a science in itself, it is more an *application* of all available sciences to the relief of suffering humanity and the prevention of disease. The clinical professors, therefore, should have a wide scientific foundation apart from practical medicine, it may be in pathology (anatomical or experimental) or in physiology (physical or chemical); the clinical teacher must be fit not only to conduct the work of his wards but also the work of his laboratories. But above all he must be a good physician, because he has to instruct the young generation in practical medicine. If he should not be thoroughly acquainted with the practice of medicine there would soon arise a discrepancy between the university teachers and professional medicine—such a disagreement as we find between scientific jurisprudence and the practice of law, and which we all deplore. For such discrepancies the student has a keen sense. The professor of clinical medicine has to consider his professorial work as his principal duty, as every other university professor does. He has to devote the main portion of his day to his hospital wards, to his teaching, and his laboratory. It is not a recommendation for a clinical professor if he has a large private practice. On the contrary, it is a pity, and it is not fair if he wastes too much of his time in consultations instead of devoting it to his university work. The limit of his private consulting practice must be left to his own conscientiousness. Should he not be permitted to have private practice at all? I think this goes too far. The clinical teacher should be in constant touch not only with the progress of science, but also with general professional life, and the practitioners too. If he should be confined entirely to his laboratory and hospital he would be liable to make mistakes and come to wrong conclusions.

The clinical professor must have his staff of well-educated assistants. The conduct of a modern medical clinic needs to-day at least one assistant thoroughly experienced in biological chemistry, one in the experimental physical methods of biology, including the investigation of the heart and the X ray work, and one in bacteriology and serology, so that he may be able to work out the Wassermann test and difficult serological diagnoses. It is an excellent plan that one assistant have charge of all questions of the blood and pathological histological examinations, and one of the diseases of the nervous system. The assistants should not be changed every year, because it takes a long time to train and develop an assistant thoroughly, and because it is obvious that an older and highly accomplished assistant is of much greater value to the clinic than a junior man. The future clinical directors will be selected from the number of the old and thoroughly trained clinical assistants. The clinical assistant knows that his future career as a professor of medicine depends mainly on his scientific work, and this gives him a great compulsion to devote himself to scientific investigation. But a school of assistants of a high degree of excellence can only flourish under the conduct of a thoroughly scientific clinical director.

If the conception of the position of the clinical teacher I have placed before you is accepted, it is obvious that he must be in charge of his wards and laboratories throughout the whole year. Under this condition alone can he conduct the work of his wards and control his assistants and his nurses with a strong hand. If the chief physician changes place every three months, or if there are too many of them in one hospital, so that every one has only a small number of beds, then not the clinical professor but the house physician or the head nurse will be the real governor, to the detriment of the hospital. The selection of a university professor for a vacant chair should not be restricted to the junior members of the same school. And this rule applies, not only to the selection of the theoretical professors, but also and especially to the clinical positions. The selection must be made from a wide field, from all universities, not only of the same country, but of the same language.

Inbreeding is the worst thing in the development of the race, and a law which is so general in nature, and whose bad effects are so carefully avoided in all realms of nature, cannot be without importance for the regeneration of a university. Fresh blood and competition with the other best centres is the chief consideration for the welfare of the universities and hospitals.

The Cost and Aim of Reform.

Is it really necessary to incur such great expenses as we have spoken of in every medical school? Would it not be possible to conduct the school for the common practitioner in the old well-established manner? No. The general medical practitioner has always and everywhere to deal with the highest good, with the health of his fellow-creatures, and he must become more and more, even in the remotest village, the promoter of public health, and therefore he must be an educated man. In his responsible vocation he must have some ideal which elevates him above the daily sorrows and disappointments of life. And he will find his refuge in his science. Only a good scientific education will enable him to follow the progress of medicine with critical understanding. Without a good scientific training he would sink into mere routine.

In all questions which are connected with educational problems we must be aware that we have to care for the future—for the next generation. A plan of reform which is only intended to meet the wants of the present day is wrong from the beginning. All our plans for reform must be broad enough to allow further expansion and accommodation to the necessities of advancement in science.

EXMOUTH MEDICAL CHARITIES.—As a result of a recent carnival held at Exmouth the sum of £100 has been divided amongst different local medical charities.

MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.

VIII.[1]—VIVISECTION.—WITCHCRAFT.—WERWOLF.

Vivisection.

THE article upon the important subject of Vivisection has been entrusted to Mr. Stephen Paget. The article is not controversial; it is simply a catena of facts; and ought, we think, to convince every clear-headed person that results of great value, both to men and beasts, have been arrived at from experimental research in connexion with living animals. Of course, there are persons who object to any and every form of experimentation upon living animals, but the vast majority of reasonable persons, with more or less reluctance, allow that in certain cases and hedged about with proper restrictions experimentation upon such animals is justifiable. Mr. Paget's article will be of value to all such who are called upon to give an account for their attitude.

Mr. Paget commences by an account of the methods of modern vivisection as employed in this country, and shows with absolute certainty that the outcry against physiology and physiologists which we are so familiar with is based upon ignorance. Part II. is a careful and lengthy *résumé* of the scientific results obtained through animal experimentation in this country and abroad. The results are grouped under two heads: (A) Physiology; and (B) Pathology, Bacteriology, and Therapeutics. For the intelligent layman, who will naturally form by far the greater part of the readers of the Encyclopædia, Mr. Paget's informing contribution will be found both interesting and educational.

Witchcraft.

The article upon Witchcraft in Vol. XXVIII. of the Encyclopædia is from the pen of Mr. N. W. Thomas, Government anthropologist to Southern Nigeria, who has also in part supplied the article upon a closely related subject—namely, Werwolf.

The belief in witchcraft is one of the most curious and saddening phases of human thought, and in its origin goes back to primitive times. Mr. Thomas reminds his readers of a matter too generally forgotten—namely, that "the modern European conception of the witch is perhaps the result of the fusion of several originally discrete ideas." The more recent conceptions of a witch are that she is a woman who has made a compact with the devil, under which she is dowered with the power of preparing love potions and of causing storms or blasting crops, of causing sickness and death, of bringing about sterility, difficult labour, or impotence, and generally of working evil in various ways. She can also turn herself into the form of an animal, generally a hare or a cat. All these functions did not become fused in one person until comparatively late in the world's history, and the early witches, such as the witch of Endor, and Canidia, as described by Horace, possessed powers not claimed unless exceptionally by the modern witch of raising the spirits of the dead—

"ut inde
Manes elicerent, animas responsa daturas."

On the other hand, the power of raising the spirits of the dead was the common property of the sorcerer, and continued even in this country as late as the middle of the seventeenth century, a notable example of one who is alleged to have possessed the power being Edward Kelley.

In classical and post-classical times Thessalian witches were considered the most expert, and many of our readers will remember the accounts given of their doings by Apuleius in his novel Metamorphosis, commonly called the Golden Ass.

In mediæval and later times sexual matters played a large part in witchcraft, and hence arose the belief in witches' Sabbaths, in the concubitus daemonum and in incubi and succubi, for a grave discussion of which we may refer the curious to a treatise entitled "Dæmonialitas," by Louis Marie Sinistrari of Ameno, written late in the seventeenth or early in the eighteenth century. Mr. Thomas considers that witches did really believe in their alleged powers, and that suggestion and possibly telepathy played a great part in the results obtained. Some of them were probably insane. No one we think will deny that in a credulous and superstitious age the power of suggestion might have great effect. If a witch, a woman honestly believed to be possessed of supernatural powers, impressed upon someone the idea that he would waste away, it is quite probable that he would begin to do so, particularly if he had in the first case consulted her in the character of a sick man; his resisting powers being further lowered he would be very likely to be carried off by some intercurrent disease. Such an occurrence is still not unknown among primitive savage peoples, and as regards sexual matters the influence of the mind upon the question of impotence or the reverse is known to every psychologist. From these facts and from the dread which they inspired it was an easy descent to the credulities and cruelties which disgraced Europe in the sixteenth and seventeenth centuries, and how we are near to such horrors even now, where education has not made much advance, is shown by the fact that so late as 1895 an unfortunate woman was burned alive as a witch in a remote district of Ireland by her ignorant neighbours. That such insanity of mind could exist in the nineteenth century is all the more astonishing when we reflect that so long ago as 1584 one man—namely, Reginald Scot, had the courage and insight to write his "Discovery of Witchcraft, Proving the Common opinions of Witches contracting with Divels, Spirits, or Familiars; and their power to kill, torment, and consume the bodies of men, women, and children, or other creatures by diseases or otherwise; their flying in the Air, &c. To be but imaginary Erronious conceptions and novelties. ....."

Werwolf.

The article found under the above title is somewhat incomplete and must be studied in connexion with that upon lycanthropy. That men and women had the power to turn themselves into animals is a commonplace of folk-lore, but though witches were commonly credited with the power of becoming cats or hares it is rare to find a woman as a werwolf or other destructive beast—e.g., a tiger or leopard. Women werwolves are, however, profoundly feared in Armenia. The origin of the belief in werwolves is obscure, but in many cases it was intensified or supported by the acts of Sadistic maniacs, who themselves believed that they committed their acts under the form of a wolf. In countries where the wolf is not such a pest as he formerly was in Europe, other animals take his place, such as the leopard in Africa or the tiger in India. The literal meaning of the word werwolf is simply man wolf, but in practice it came to be applied as meaning a man wolf with a lust for destruction and not simply a human being transformed into a wolf by sorcery such as the victims of Circe.

There is one passage in the Encyclopædia article about which we think that doubt is allowable. The authors, Mr. N. W. Thomas and the late Mr. J. F. M'Clennan, say quite correctly that all werwolves were not viciously disposed towards mankind. But they then go on to give as examples the wolves mentioned by Baronius who in 617 tore to pieces some heretical friars, and also the wolf which guarded the head of St. Edmund the Martyr, King of England. Is there any authority for supposing that these wolves were transformed men and not simply animals acting under the guidance of God in the same way that the lion slew the false prophet or the bears devoured the rude school children as related in the Scriptures (compare the wolf which repented at the preaching of St. Francis and lived a gentle life)? Friendly animals are of course a well-known feature of folk-lore, and all saints, both Christian and others, are reported to have had, and most probably did have, a remarkable influence over animals. As a whole the two articles (Lycanthropy and Werwolf) are of much interest, and if the sexuo-psychological side of the question has been but just mentioned, this is only what is to be expected in a treatise intended for the general reader.

[1] Articles I., II., III., IV., V., VI., and VII. were published in THE LANCET of Feb. 25th (p. 530), March 4th (p. 609), 11th (p. 692), and 25th (p. 828), April 1st (p. 897) and 15th (p. 1026), and Oct. 7th (p. 1035), 1911, respectively.

THE Aberdeen University Club, London, will hold its annual dinner on Wednesday, Nov. 15th, at 7 P.M., in the Trocadéro Restaurant, Piccadilly-circus, London, W., with Dr. Albert Westland in the chair.

MEDICINE AND THE LAW.

Medical Men and the Midwives Act.

THE death of a woman at Leicester led recently to an inquest at which a medical man's conduct was made the subject of an expression of unfavourable opinion by the jury owing to circumstances arising mainly out of the operation of the Midwives Act, for which he was in no way responsible. The deceased woman had apparently engaged for her approaching confinement a midwife 68 years of age, and it must here be pointed out that all practising midwives were allowed to be registered under the Midwives Act when it first came into force, subject to their bearing "a good character." Two months before she expected her confinement the deceased was taken ill with hæmorrhage and severe pains and her neighbours summoned the midwife, who, however, pronounced the symptoms to be of no importance and not due to the near approach of confinement. The neighbours, however, as the woman continued ill, sent for a medical man who happened to be temporarily occupying the practice of a deceased practitioner on behalf of the executors. He arrived, and on learning the nature of the case, according to the story of the neighbours mentioned, pointed out that it was one for which his fee would be a guinea, and said that if that sum was not forthcoming application should be made to the parish medical officer. According to the medical man himself he had no information to lead him to suppose that the patient was in a serious condition, and he would not have hesitated to attend her had he thought that his assistance was urgently required. He was aware that a midwife had had to do with the case he was under the impression that another medical man was also concerned in it, and he had not been sent for under the midwife's advice, in which case he would have been entitled to a notice from her as to the reasons for which he was wanted. It may be also pointed out here that a medical man attending on such an occasion as that described, without the prescribed particulars as proof of the midwife having advised that he should be sent for, would very possibly find a difficulty in obtaining his fee from the guardians, even if they were willing to pay such fees where the regulations of the Central Midwives Board had been complied with. In the case in question two other medical men afterwards attended, but the patient died after the birth of a stillborn child, and the question of whether her decease was in any way due to the delay consequent upon the refusal of the first medical practitioner, was prominently before the jury. The coroner, in summing up, dealt with the conduct of the midwife, who clearly failed to recognise the nature of the case and to deal with it in accordance with the rules imposed upon her, and he also referred to the position of the medical man, acknowledging that there is no obligation upon the medical profession to practise without remuneration. He appears, however, to have laid the evidence before the jury as offering two alternatives. That either the medical man knew the grave condition of the deceased, in which case his refusal to assist her without a fee being first paid would be inhuman, or that he failed to realise the gravity of her condition, which the neighbours had appreciated already and which another medical man recognised later, and that in that case he was guilty of a grave error of judgment. This, it seems to us, was to impale unfairly the medical man upon one horn or other of a dilemma. As a matter of fact, he made no examination of the woman, and had no reason whatever to believe that the case was one of imminent danger.

Trials for Infanticide.

In THE LANCET of Oct. 28th, p. 1223, reference was made to some observations of Mr. Justice Scrutton upon the sympathy extended by juries to prisoners in cases of alleged infanticide. Since then, before Mr. Justice Ridley at the recent Derbyshire assizes, two women, a mother and daughter, have been tried for murder and convicted of concealment of birth in a case which shows the difficulty of establishing the commission of the capital offence, owing to the usual circumstances of delivery upon such occasions, and apart from the sentiment of pity which may conduce to acquittal. The story told by the mother in the witness-box was to the effect that her daughter returned from service without her condition being suspected by her parent, and was afterwards found by her unconscious upon the concrete floor of the kitchen with a newly-born child lying under her dead. There was an apparently contradictory statement by the same witness to a medical witness that the child had lived about ten minutes, which she explained as based upon what her daughter had said on recovering consciousness. The daughter also had told the police that the child had received no injury at birth and was never suckled. That the body had been secretly disposed of was not disputed. The medical evidence was of importance, as there were two fractures of the child's skull, and Dr. R. G. Chase, called for the prosecution, cited authorities to show that by experiment it had been found that in one case only out of 30 a double fracture was obtained by dropping the bodies of stillborn infants from a height of 30 inches upon a hard floor. This evidence obviously was not sufficient to establish the impossibility of accident in the case before the jury, although it undoubtedly pointed to the probability that the death of the child had been due to criminal violence. In these circumstances the possibility of the skull having been fractured through the child falling to the ground in the process of self-delivery was naturally dwelt upon by counsel for the defence, and in the result, as has been stated above, both prisoners were acquitted of murder and convicted of concealment of birth only. Mr. Justice Ridley, however, passed a sentence upon each of them of 18 months' hard labour, observing that he was not disposed to believe anything that they had said in the witness-box. He told them that the child's body bore the evidence of very serious injuries, and that they must remain suspected of having brought them about. Either these people are innocent or guilty of murder. The jury acquitted them, but the judge has taken the unusual step of placing them for ever under the stain of the greater crime.

The Case of Miss Holder.

At the recent Devon assizes held at Exeter Miss M. M. Holder, 20 years of age, was convicted of stealing a number of articles the property of Mr. C. O. Baines and his wife, and on being convicted was sentenced to 18 months' imprisonment with hard labour. The admitted facts and the nature of the defence have attracted considerable attention to the case, and both were of unusual character. To put them briefly, Miss Holder committed the offence by going to the house of Mr. and Mrs. Baines while they were out and the house was empty, but with the knowledge of Mrs. Baines and with a latchkey supplied by her. She had already borrowed a cardboard box which was in the house in order to send away a hat in it, and she was seen to leave the house on the occasion in question carrying this box, which appeared to be heavy. She tried to send it away by parcels post, but it was beyond the prescribed weight for that purpose, so she left it at the railway station, where it was taken possession of by the police and found to contain besides a coat belonging to the accused sundry articles, stated to be of silver or silver-plated, including a kettle, coffee-pot, teapot, sugar-basin, cream-jug, jam-dish, and butter-dish. The defendant went into the witness box and told a story which had been already suggested in the cross-examination of the prosecutor, but which was entirely uncorroborated, of amatory advances made to her on frequent occasions by Mr. Baines; and she frankly suggested that out of revenge for her threats to inform his wife of the misconduct she thus alleged, he had had the teapot and other articles placed in the cardboard box, and also that rings belonging to Mrs. Baines which were found in a box at her home by the police in company with the prosecutor, were at that time put there by him. She accounted for not having attached importance to the weight of the cardboard box when she took it from the house, and when she was proved to have obtained an errand boy to take it to the railway station, by saying that she was then unwell and believed that on that account it seemed heavier than it really was. The jury in convicting the prisoner recommended her to mercy on the ground that they could find no motive for the thefts, and it may be mentioned that she is stated to be the adopted child of a lady of some means, and to have been driven to the court in a carriage and pair—at any rate, no suggestion of any pecuniary need was made. After the verdict a medical man was called who gave evidence to the effect that,

in his opinion, the prisoner was subject to hysteria, and in passing sentence the Lord Chief Justice, after saying to the prisoner, "You made atrocious charges against an honest man and a friend," is reported as having used these words, "You were not, perhaps, in your right mind at the time of the thefts, but undoubtedly you stole the goods." Presumably the attention of the Home Office will be called to his utterance and to the salient features of a crime, the futility of which and the hopelessness of it escaping detection, coupled with the nature of the defence raised, would seem to justify the suggestion that it was committed by a person not in her "right mind." No doubt the defence was insisted upon and excluded any other, but the passing of a sentence of hard labour upon a prisoner who, according to the expressed view of the judge sentencing her, may not have been in her right mind, even if it be followed by other measures to meet the case, hardly seems desirable or consistent with justice. The convict's line of defence makes it impossible for her to expect much public sympathy, but medical men will view the matter otherwise.

A Medical Man and the Justifiable Use of Force.

According to the evidence given at the Brentford police court recently Mr. George Phillips, a medical man practising in West Ealing, had occasion to remonstrate with the husband of a female patient in the course of last year on the ground that his conduct had caused injury to her health. This was resented by the husband to such an extent that many months afterwards he summoned the medical man to his house by telephone, and having got him there barred his exit and tried to insist upon retractation of what had been said and an apology. Mr. Phillips refused to tender either, and after being called abusive names by his captor had to seek an exit by throwing the angry husband on to a couch, on account of which forcible proceeding he was summoned for assault. The Bench, however, after hearing the prosecutor's evidence, at once said that the only question was whether the defendant used such force as was necessary to enable him to leave the house, and being of the opinion that that was all he had done dismissed the case. It is extremely rare, we are glad to say, that we have to record such resentment against a medical man for speaking his mind.

Old Age Pensions and Starvation.

At an inquest held by Mr. Troutbeck at the Battersea Coroner's Court recently an account was given of the life of an aged couple which illustrates an undoubted danger which follows in some cases upon the granting of old age pensions, where the recipient is unable to supplement them through the goodwill of relatives or by other means. The deceased was a woman receiving an old age pension and living with her husband, who will not attain the age entitling him to a pension until next June. The two shared a single room, for which they paid 3*s.* weekly rent, and their income consisted of the 5*s.* pension of the wife, supplemented by such casual additions as the aged husband could earn by window cleaning, gardening, and other casual employment of a precarious nature. They had, in fact, 1*s.* per week each for food, and the pension which they shared, coupled, no doubt, with the prospect of the husband becoming entitled to one in the near future, kept them both out of the workhouse and the old woman from the infirmary. She had been unable to do anything for herself for 12 months, and her husband, with the aid of their landlady, had attended to her wants as best he might. Dr. L. Freyberger, giving the result of the post-mortem examination which he had made, deposed that death was due to heart failure, accelerated by acute inflammation of the lungs and want of food. He also stated that the husband, who was quite unfit to give his wife the attention necessary in her condition, was suffering from senile decay. The struggle of the poor to keep out of the workhouse must always evoke a measure of sympathy, and the rates are saved through their endurance of semi-starvation. At the same time the 5*s.* paid by the State can hardly be said to be well expended upon those persons whom it tempts to prolong a miserable existence in squalid and insanitary homes without any possibility of being able to provide for themselves reasonably decent maintenance.

THE BOARD OF EDUCATION AND MEDICAL INSPECTION AND TREATMENT OF LONDON SCHOOL CHILDREN.

THE receipt of an important letter from the Board of Education declining to sanction proposed extensions of the present scheme for the medical treatment of London school children was reported to the Education Committee of the London County Council on Nov. 8th. In July the Council decided to invite the Board's approval of agreements with 10 hospitals and 13 committees of local medical practitioners.[1] In 10 cases the proposed agreements with committees of medical practitioners were in respect of new centres to be established.

The Board of Education in its letter said that the proposed establishment of these centres constituted a very large extension of the Council's scheme of treatment, and while the Board fully appreciated the desire to make further and continuous progress towards the provision of a complete scheme it appeared doubtful whether the Council would be wise in committing itself at this juncture to such an extensive development of this single type of remedial agency. The reorganisation of the Council's arrangements for the administration of medical inspection and treatment was a matter of the first importance to the school medical service of London. Though the Board did not suggest that all extension of the London treatment scheme should be postponed pending the reorganisation, it appeared desirable that until the new organisation had been established and the responsible officer (who it was understood would combine the offices of county medical officer of health and school medical officer) had had time to consider and advise the Council on the matter, any extensions of the work should be confined to rather narrow limits, and so far as they were immediately necessary should be undertaken only on a provisional basis.

The Board was not satisfied that the establishment of a large number of treatment centres, conducted under conditions similar to those existing at the Norwood and Wandsworth centres, was in all respects desirable. The Board recognised that much valuable work had been done there, but it had regarded the existing organisation of those centres as tentative and experimental, and doubted whether at the present time it was wise to occupy so much ground in all parts of London by this particular form of agency, the establishment of which might prejudice the development of other agencies more appropriate to the circumstances, and better fitted to serve as a basis of a complete and permanent system. Indeed, the Board held that the constitution of these centres must be modified in several important respects if they were to form an integral part of the London system of coördinated inspection and treatment; and it was almost essential that in introducing the modifications required, the Council should have the advice and assistance of the chief medical officer who would be appointed shortly.

The Board would be very reluctant to refuse or even to delay provisional sanction to any well-considered extension of the Council's scheme of treatment which would be put into operation at once and be used for the immediate relief of children whose defects had been ascertained but who could not now obtain treatment because the existing means at the disposal of the Council were inadequate. But from the information before it and after considerable inquiry the Board was not satisfied that the existing conditions in respect of medical inspection and medical treatment in London were such as to justify the particular form of development on such an extensive scale as the Council proposed for immediate adoption, and therefore some postponement was preferable. It seemed hardly possible for such establishment to be effected within the next three months as the Council suggested. Not one of the new centres, except that at Deptford, was in fact as yet in existence; nor had any definite arrangements yet been formulated in regard to the acquisition of premises, the appointment of the medical staff, or the precise control and management of the new medical treatment centres. It would appear, therefore, that the postponement of the adoption of these extensions for a few months, pending the intended reorganisation of the Council's administrative

[1] THE LANCET, July 22nd, 1911, p. 246.

arrangements which was to take effect in less than three months from the end of October (the date of the Board's letter), would not involve the loss of any immediate benefits to the children, but would be more likely to result in the ultimate adoption of a scheme more closely coördinated with the Council's system of medical inspection, more definitely under the supervision of the authority, and more directly fitted to the needs of the area as a whole. The ultimate gain to the children resulting from the establishment of such a scheme would far outweigh any disadvantages which might arise from temporary postponement. In these circumstances, it appeared very desirable that the matter should be further considered by the Council, and the Board had decided therefore that it would not be justified at this stage in sanctioning the proposed large extension of the scheme.

The Board intimated that it would be prepared to sanction the proposed arrangements with the committee of the Deptford Children's Health Centre, and the continuance until Dec. 31st, 1912, of the arrangements for the medical treatment of children at the nine hospitals and three treatment centres (Norwood, Wandsworth, and Woolwich), in respect of which sanction had already been given for the year ending Dec. 31st, 1911. This sanction covered the proposed modifications and extensions of the arrangements with certain of these institutions, and was subject to the Council furnishing the Board before the end of this calendar year with a statement to the effect that the committees of each of the hospitals and treatment centres concerned had consented to the continuance and extension or modification of the existing agreements. The Board would also require to receive from the Council not later than Oct. 31st, 1912, a full report by the Council's school medical officer on the working of the arrangements now sanctioned.

The Children's Care Subcommittee, in reply to this letter, urged that as the scheme under discussion was submitted in response to the expressed wishes of the Board, it could not be intended that the Council should defer the question of any further provision for medical treatment until it had considered the matter in relation to the reorganisation of the general medical work of the Council. The subcommittee read the letter of the Board of Education as implying that, while the Council's proposals as a whole could not be agreed to, the Board would be willing to consider individual proposals of an urgent nature on their merits.

The Education Committee decided, without discussion, to write to the Board inquiring whether individual proposals for providing treatment might be submitted pending the reorganisation of the Council's medical service.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 8061 births and 4182 deaths were registered during the week ending Nov. 4th. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 13·3 in the ten preceding weeks, slightly rose to 13·5 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 14·3, or 0·1 per 1000 above that recorded in London during the same period. The death-rates in the 77 towns last week ranged from 4·5 in Devonport, 6·4 in King's Norton, and 6·8 in Hornsey and in Dewsbury, to 19·3 in Middlesbrough, 20·5 in Great Yarmouth, 20·6 in West Bromwich, and 20·8 in Bootle. The 4182 deaths from all causes in the 77 towns were 54 in excess of the number returned in the previous week, and included 301 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 334 in the ten preceding weeks. Of these 301 deaths, 128 resulted from infantile diarrhœa, 56 from diphtheria, 36 from measles, 35 from enteric fever, 30 from scarlet fever, and 16 from whooping-cough, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 1·0 per 1000, against 1·3 and 1·1 in the two previous weeks. The deaths of infants under 2 years of age attributed to diarrhœa, which had continuously decreased from 2714 to 164 in the ten preceding weeks, further declined to 128 last week, and caused the highest annual death-rates of 1·6 in Birkenhead and in West Hartlepool, 1·7 in Walsall, 2·0 in Stockton-on-Tees, and 2·9 in Warrington. The deaths referred to diphtheria, which had been 44, 60, and 46 in the three preceding weeks, rose to 56 last week; 21 deaths were recorded in London and its suburban districts, 4 in Leeds, and 3 in Preston. The fatal cases of measles, which had increased from 19 to 48 in the five preceding weeks, declined last week to 36, and included 12 in London, 4 in Nottingham, and 3 in Burnley. The deaths attributed to enteric fever, which had been 39, 48, and 28 in the three previous weeks, rose last week to 35, and included 10 in London and its suburban districts, 4 in Hull, and 2 each in Liverpool, Bradford, Leeds, and Newcastle-on-Tyne. The deaths referred to scarlet fever, which had averaged 14 in the four preceding weeks, rose last week to 30, and of these 3 were registered in London, 3 in Stoke-on-Trent, and 2 each in Birmingham, Coventry, Nottingham, Liverpool, Leeds, and Sheffield. The fatal cases of whooping-cough, which had been 35, 25, and 30 in the three preceding weeks, declined last week to 16, and was the lowest number recorded in any week of the current year; 3 deaths were recorded in London, 2 in Great Yarmouth, and 2 in Liverpool. The number of scarlet fever patients in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 2180 in the nine preceding weeks, had further advanced to 2189 on Saturday last; 269 new cases of this disease were admitted to these hospitals during the week, against 355, 344, and 297 in the three previous weeks. These hospitals also contained on Saturday last 1178 cases of diphtheria, 161 of whooping-cough, 146 of enteric fever, and 85 of measles, but not one of small-pox. The 1140 deaths from all causes in London last week were 8 in excess of the number in the previous week, and included 170 which were referred to diseases of the respiratory system, against 210, 218, and 210 in the three preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 150 and 158 in the two preceding weeks, declined to 144 last week, and 355 inquest cases were registered. The causes of 24, or 0·6 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Portsmouth, and in 52 other smaller towns. The 24 uncertified causes of death during the week under notice included 5 in Liverpool and 2 each in Birmingham, Bootle, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 793 births and 538 deaths were registered during the week ending Nov. 4th. The annual rate of mortality in these towns, which had been 15·7 and 16·7 per 1000 in the two preceding weeks, declined to 16·4 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·0 per 1000, and was 1·7 per 1000 above the mean death-rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 9·3 and 13·2 in Paisley and Greenock to 18·0 in Dundee and 18·3 in Glasgow. The deaths from all causes in the eight towns were 10 fewer than the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against 47 and 52 in the two preceding weeks; of these 47 deaths, 15 resulted from measles, 12 from diarrhœal diseases, 11 from diphtheria, 5 from whooping-cough, and 4 from scarlet fever, but not one from small-pox or from enteric fever. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·4 per 1000, and was 0·4 per 1000 above the mean death-rate from the same diseases in the 77 large English towns. The deaths attributed to measles, which had steadily risen from 1 to 12 in the five preceding weeks, further increased to 15 last week, and comprised 8 in Glasgow, 6 in Aberdeen, and 1 in Leith. The deaths referred to diarrhœal diseases, which had been 41, 20, and 19 in the three previous weeks, further declined last week to 12, all but one of which were of infants under two years of age; 5

deaths were recorded in Glasgow, 3 in Dundee, and 2 in Edinburgh. The 11 fatal cases of diphtheria were 2 in excess of the average in the four preceding weeks, and included 6 deaths in Glasgow. The 5 deaths referred to whooping-cough corresponded to the average in the four previous weeks, and comprised 4 deaths in Glasgow and 1 in Perth. The 4 deaths referred to scarlet fever were 3 fewer than the number in each of the two preceding weeks, and included 2 in Glasgow. The deaths referred to diseases of the respiratory system, which had been 80, 78, and 111 in the three preceding weeks, rose again last week to 116, and were 32 in excess of the number in the corresponding week of last year. Of the 538 deaths from all causes in the Scotch towns last week, 158, or 29 per cent., were recorded in public institutions, and 19 deaths were attributed to different forms of violence. The causes of 18, or 3·3 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 568 births and 378 deaths were registered during the week ending Nov. 4th. The annual rate of mortality in these towns, which had declined from 19·6 to 17·1 in the four preceding weeks, was again equal to 17·1 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·1 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 14·3 per 1000, while in the eight Scotch towns it was equal to 16 0. The annual death-rate last week was equal to 20·4 in Dublin (against 13·1 in London), 15·1 in Belfast, 22·5 in Cork, 19·2 in Londonderry, 17·7 in Limerick, and 19 0 in Waterford; while in the 16 smallest of these Irish towns the annual death-rate did not exceed 11·0 per 1000. The 378 deaths from all causes were 1 in excess of the number in the preceding week, and included 40 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 47 in the seven preceding weeks; of these 40 deaths, 24 resulted from diarrhœal diseases, 6 from measles, 4 from enteric fever, 4 from scarlet fever, 1 from whooping-cough, and 1 from diphtheria, but not one from small-pox. These 40 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·8 per 1000; in the 77 English towns the mean death-rate from these diseases did not exceed 1·0 per 1000, while in the eight Scotch towns it was equal to 1·4. The deaths attributed to diarrhœal diseases, which had steadily decreased from 121 to 27 in the seven preceding weeks, further declined to 24 last week, and included 21 of infants under two years of age; 15 deaths were recorded in Dublin, 3 in Cork, 2 in Belfast, and 2 in Waterford. The 6 deaths from measles were equal to the number in the previous week; 4 deaths were registered in Dublin and 2 in Cork. Of the 4 deaths referred to enteric fever, which were equal to the average in the five preceding weeks, 3 occurred in Dublin and 1 in Belfast. The 4 fatal cases of scarlet fever were 2 in excess of the number in the previous week, and comprised 2 in Dublin and 2 in Belfast. The fatal case of whooping-cough was returned in Dublin, and that of diphtheria in Waterford. The deaths referred to diseases of the respiratory system, which had been 66 and 57 in the two preceding weeks, rose to 77 last week. Of the 378 deaths from all causes in the Irish towns last week, 122, or 32 per cent., were recorded in public institutions, and 7 deaths were attributed to different forms of violence. The causes of 25, or 6·6 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·6 per cent. in the 77 large English towns, and was equal to 3·3 per cent. in the eight Scotch towns.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. Alfred Miller has been elected Registrar of the Royal College of Surgeons in Ireland in the room of Mr. G. F. Blake, retired.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeon: W. L. Martin to the *President*, additional, for temporary service in Medical Department, Admiralty. Surgeons: E. M. Browne to be lent to Shotley Training Establishment; J. H. McDowall to the *Pelorus*, for voyage out, and to the *Perseus*, on recommissioning; and P. F. Minett to the *Lord Nelson*.

ARMY MEDICAL SERVICE.

Colonel Robert H. Forman is placed on retired pay (dated Nov. 2nd, 1911). Lieutenant-Colonel Alexander F. Russell, C.M.G., from the Royal Army Medical Corps, to be Colonel, vice R. H. Forman (dated Nov. 2nd, 1911).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Thomas W. O'H. Hamilton, C.M.G., retires on retired pay (dated Nov. 4th, 1911). Major Charles A. Young to be Lieutenant-Colonel, vice A. F. Russell, C.M.G. (dated Nov. 2nd, 1911).

Colonel H. J. R. Moberly, principal medical officer of the Bangalore and Southern Brigades, has been struck off the strength of the Indian establishment with effect from Oct. 29th. Lieutenant-Colonel S. Westcott, C.M.G., commanding the station hospital at Chakrata, has been detailed as Senior Medical Officer on board the troopship s.s. *Dongola*, which left Bombay for Southampton on Oct. 26th. Lieutenant-Colonel M. J. Sexton has been placed under orders to proceed to South Africa for a tour of service during the ensuing trooping season. Lieutenant-Colonel T. Daly has been selected to command the Station Hospital at Peshawar. Lieutenant-Colonel H. H. Brown, from Murree, Second (Rawal Pindi) Division, has been detailed for a tour of duty at Aden, in succession to Lieutenant-Colonel R. L. R. Macleod, returning to England on the troopship s.s. *Plassy* on Nov. 9th from Bombay. Lieutenant-Colonel R. H. Penton has been appointed to command the Station Hospital at Poona. Lieutenant-Colonel R. Kirkpatrick has been transferred from Devonport to Egypt. Lieutenant-Colonel W. A. Morris, in charge of the military hospital at Cawnpore, has been detailed for duty at Allahabad. Major G. W. Tate, recruiting medical officer at Dublin, has been appointed Medical Inspector of Recruits to the Irish Command, in succession to Lieutenant-Colonel M. L. Hearn, who has proceeded to Ceylon as Senior Medical Officer. Major B. J. Inniss, from Gravesend Military Hospital, has been posted to Belfast to take over the charge of the Military Hospital at that station with effect from Dec. 1st next. Major W. E. P. V. Marriott, on return from Gibraltar, has been ordered to Ireland, and on arrival will be posted to the Dublin District. Major H. S. Roch, Adjutant of the Royal Army Medical Corps School of Instruction at Leeds, has been selected for appointment as Clinical Pathologist, South African Command. H.E. the Commander-in-Chief has sanctioned one year's extension of Indian tour of service to Major F. Smith, D.S.O., specialist sanitary officer, Second (Rawal Pindi) Division. Major E. M. Hassard has been selected to command the Station Hospital at Lahore Cantonments. Major W. P. Gwynn, from Quetta, has been appointed for duty as Medical Embarkation Officer at Karachi during the ensuing trooping season. Major W. A. Woodside has been detailed for a tour of service in India, and on arrival will be appointed to the Seventh (Meerut) Division of the Northern Army. Major F. J. W. Porter, D.S.O., on the closing of Lodmoor Camp, has joined at Cosham for duty. Captain E. P. Lauder, from Aldershot, has taken up duty at Cork. Captain H. H. J. Fawcett has been appointed Adjutant of the Home Counties Division, Royal Army Medical Corps School of Instruction, in succession to Captain F. M. Parry, who has completed his three years' tenure of the appointment. Captain B. A. Craig, Captain W. J. E. Bell, and Captain H. M. J. Perry, on termination of their tour of foreign service at Hong-Kong, have been directed to return home. Captain A. Dawson has been appointed Specialist in the Prevention of Disease and placed in charge of the Enteric Fever Convalescent Depôt at Wellington, Madras Presidency. Captain R. B. Black, from the Royal Army Medical College, has taken up duty with the Egyptian army with the local rank of Bimbashi. Captain A. J. Williamson,

specialist in advanced operative surgery at the Royal Herbert Hospital, Woolwich, has been placed under orders by the War Office for a tour of service in the Straits Settlements. Captain C. W. E. S. Fawcett, commanding the station hospital at Thayetmyo, Burma, has been detailed for duty on the troopship s.s. *Dongola*, which left Bombay on Oct. 26th. Captain L. L. G. Thorpe, from West Down, has joined for duty at the Royal Victoria Hospital, Netley. Captain T. S. Dudding has been appointed Company Officer at Colchester, in succession to Captain F. M. H. Ommanney. Captain W. S. Crosthwait, on the closure of Moore Park Camp, has been posted to Fermoy. Captain F. Forrest, at present serving at Bangalore, has been granted eight months' general leave of absence home from India with effect from Dec. 1st. Captain C. R. Sylvester-Bradley has been appointed Adjutant to the Royal Army Medical Corps School of Instruction at Cosham. Approval has been given by the Secretary of State for War for the employment of Lieutenant C. Robb, at present serving at the Curragh, with the Public Health Department of the Government of Egypt. Lieutenant G. H. Stack has taken up duty in the London District. Lieutenant R. C. Priest, in medical charge of the headquarters staff and families at Colchester, has been granted one month's leave of absence prior to embarkation for a tour of service in India. Lieutenant E. C. Lambkin, from the Guards Depôt at Caterham, has joined for duty at the Military Hospital, Hong-Kong. Lieutenant F. W. M. Cunningham, from Donard Camp, has taken up duty at the Curragh.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions of officers of the Indian Medical Service:—

Captain to be Major (dated July 27th, 1911): Michael Harris Thornely.

Lieutenants to be Captains (dated August 1st, 1911): Archibald Campbell Munro, Ram Nath Chopra, Alfred Geddes Tresidder, Gordon Gray Jolly, Alister Argyll Campbell McNeill, Robert Long Gamlen, Abdus Sattar Khan, George Frederick Graham, Maneck Dhunjishaw Wadia, Taylor David Murison, Sohrab Shapoorji Vazifdar, John Joseph Harper Nelson, Edward Selby Phipson, Fleet Floyd Strother Smith, Arthur Jessop Symes, and Thomas Crawford Boyd.

The King has also approved of the retirement of Lieutenant-Colonel John Lawrence Van Geyzel (dated July 9th, 1911).

Lieutenant-Colonel M. A. T. Collie has been appointed to officiate as Surgeon to the Gokuldas Tejpal Native General Hospital, Bombay, during the absence on leave of Lieutenant-Colonel J. C. Hojel. Lieutenant-Colonel J. K. Close has taken up duty as Civil Surgeon at Allahabad. Lieutenant-Colonel G. H. Baker has been appointed a Civil Surgeon of the First Class, in succession to Lieutenant-Colonel J. F. MacLaren, retired. Lieutenant-Colonel J. M. Cadell, civil surgeon of Ghazipur, has been granted privilege leave, combined with furlough, for a total period of one year and four months. Major J. M. Woolley, senior medical officer at Fort Blair, has been appointed an Assistant Superintendent of the Settlement by the Government of India. Major G. Hutcheson, civil surgeon of Aligarh, has been placed in medical charge of the Bulandshahr district. Major J. Penny, Bengal Presidency, has been granted three months' extension of his leave by the Right Honourable the Secretary of State for India. The services of Captain T. S. B. Williams have been placed at the disposal of the Foreign Department of the Government of India. Captain J. Morison has taken up duty as Assistant to the Director of the Bombay Bacteriological Laboratory during the absence on leave of Captain J. Cunningham. Captain H. S. Hutchinson has been appointed to officiate as civil surgeon at Karachi during the absence on special duty of Lieutenant-Colonel B. B. Grayfoot. The services of Captain W. Tarr have been permanently placed at the disposal of the Chief Commissioner of the Central Provinces. Captain A. J. H. Russell has been selected for appointment by H.E. the Commander-in-Chief in India to the Substantive Medical Charge of the 18th King George's Own Lancers at Meerut, in succession to Captain A. S. M. Peebles, transferred to the civil department. Captain F. W. Cragg has joined the King Institute, Guindy, as Assistant Director. Captain J. M. A. MacMillan, on completion of special duty at Pachmarhi, has been appointed Civil Surgeon to the Hoshangabad district. Captain E. W. Browne, at present doing duty at the General Hospital, Madras, has been granted 15 months' combined and study leave. Captain W. A. Justice has taken up duty as Officiating Sanitary Commissioner of Madras Presidency. Captain W. F. Byrne has been appointed Special Plague Medical Officer in the Pegu District. Captain J. D. Graham has taken up duty in the United Provinces of Oudh and Rohilkhand.

TERRITORIAL FORCE.

The undermentioned officers of the Royal Army Medical Corps are appointed Staff Officers to Administrative Medical Officers of Territorial Divisions: Major Gerald T. Rawnsley (dated March 1st, 1911), Major William D. Erskine (dated March 1st, 1911), Lieutenant-Colonel James Will (dated April 1st, 1911), Major Charles A. Young (dated April 1st, 1911), and Captain Dermot O. Hyde (dated April 1st, 1911).

PROMOTION IN THE NAVAL MEDICAL DEPARTMENT.

It was a very common complaint against all "Services" that their rule for promotion was "seniority tempered by selection," with the accent rather on the "seniority," and that consequently many officers who attained to the senior ranks had indeed had creditable and even distinguished services to their credit, but had now lost touch with the modern achievements of their sciences and had no longer the old eagerness. The Admiralty, having evidently taken this complaint to heart, recently declared its intention for the future to promote medical officers to the senior ranks by selection, for ability and merit, with no word about seniority. The first subsequent promotion it has now made by advancing Deputy Surgeon-General W. W. Pryn, and this choice will commend itself, as this officer has held very important offices, and is besides known to the profession generally for the capable papers he has contributed to the annual reports on the health of the navy. His promotion from thirtieth on the list should give to junior officers the encouragement and incentive they have often complained to us they lacked. A somewhat similar advancement of juniors to the new rank of superintending sister in the Naval Nursing Service has provoked a complaint to the *Naval and Military Record* of Oct. 18th, an expression of natural disappointment on behalf of those passed over. Such hardships are, we fear, inevitable in all progress, but we trust that promotion by selection, thus boldly introduced, will lead all ranks to throw themselves more hopefully into the discharge of their duties, with a resulting greater efficiency within the medical service, and consequent higher appreciation from brother officers and the profession at large.

THE OFFICERS' TRAINING CORPS.

The Army Council announces that in future candidates for employment with medical units of the Officers' Training Corps will be appointed to commissions in the Territorial Royal Army Medical Corps, supernumerary for service with the Officers' Training Corps. In the case of undergraduate officers who are not qualified as practitioners under the Medical Act, they will be appointed "on probation" until they have obtained the necessary diploma.

ACCELERATED PROMOTION IN THE INDIAN MEDICAL SERVICE.

The Secretary of State for India has recently decided that if an Indian Medical Service officer was unable to obtain study leave, and was thereby prevented from qualifying for accelerated promotion to the rank of major, he might qualify at any time up to the end of his sixteenth year of service. In that case his promotion would be antedated. This concession has now been extended with retrospective effect to all majors whose commissions are dated July 29th, 1893, or later, and who have undergone qualifying courses before the end of their sixteenth year.

HONORARY PHYSICIAN AND HONORARY SURGEON TO HIS MAJESTY THE KING.

It has been decided that future appointments of honorary physician and honorary surgeon to His Majesty the King shall be held by medical officers on the Active List, and that such appointment shall be relinquished on retirement from the service. This rule has hitherto only been applicable to those officers of the Royal Army Medical Corps appointed in or after the year 1906, but it has now been extended to the Indian Medical Service. According to the Royal Warrant, six of the most meritorious officers of the Royal Army Medical Corps and six of the Indian Medical Service are

selected for appointment as honorary physicians, and six others of each service respectively selected for appointment as honorary surgeons to the King. Any officer so appointed who is under the rank of colonel may be promoted to the brevet rank of colonel.

FAIR PLAY FOR TERRITORIALS.

In our issue of April 22nd last we invited attention to a pamphlet with the above title, issued by Lieutenant-Colonel J. J. de Zouche Marshall, in which he described his proposals for invigorating and expanding the Territorial Force by a system of payment according to scale, in proportion to the pay of the Regular Army. Officers and men would be paid so much per hour for every hour spent in actual drill and instruction. This amount, calculated at one-twelfth of the pay of the regular forces (who are presumed to be paid for 12 hours' work per day), would work out at 3*d.* for a private, 5*d.* for a sergeant, 1*s.* 2*d.* for a captain, and so on. Lieutenant-Colonel Marshall has now brought out a second edition of this pamphlet,[1] in which he has expanded his argument with additional illustrations, together with some rather irrelevant matter. It appears to have been objected that the pay above mentioned was not high enough to attract men of the working classes, who receive even as day labourers 7*d.* an hour. Lieutenant-Colonel Marshall replies to this by showing that the working day of the regular soldier is really but an eight-hour day, and therefore that the pay works out at 5*d.*, instead of 3*d.*, an hour; and so on for the other ranks in proportion. It might also be admitted that the work of the soldier is neither so arduous nor so continuous as that of the class of labourers generally with whom comparison is made. However that may be, Lieutenant-Colonel Marshall still considers that 3*d.* an hour for a private, and proportional sums for other ranks, would attract the men that are needed. As justification for the increased cost he maintains that for an additional half month's army pay and allowances the nation would obtain 11 months' steady progressive training. The total cost he estimates at £249,828, which would secure 48 one-hour drills by a force of 312,422 officers and men. Lieutenant-Colonel Marshall has withdrawn from the National Service League, and devotes several pages of his second edition to a criticism of its methods. Into this question we cannot follow him, but we again commend his proposals to Territorial officers, and especially to those of medical units. Experience only can show whether the success he has himself obtained in his own corps can be repeated by others; but the plan seems to be exceedingly well worked out, and to be fully deserving of a thorough trial. All practical details are given in the pamphlet already referred to.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the November issue of this journal Captain P. S. Lelean criticises the use of quinine as a malarial prophylactic. He does not suggest that quinine prophylaxis, if properly safeguarded, has no value in any circumstances, but he considers it essential that a protest should be made against the view that in the wholesale administration of prophylactic quinine we have a simple and royal road to malaria prevention warranting the withdrawal or omission of all other measures. Interesting papers are The Work of Divisional Medical Units in the Field, by Colonel T. P. Woodhouse, and Pathology and Clinical Medicine, by Major W. S. Harrison, who points out that it is impossible to practise medicine properly without having constant recourse to the help of the pathological laboratory. A note which is worthy of attention is contributed by Major F. J. W. Porter, D.S.O., on the Aseptic Treatment of Burns and Scalds. Being dissatisfied with oily applications in such cases, Major Porter devised a method of cleaning the affected surface under an anæsthetic, afterwards applying sterile gauze, with very satisfactory results.

[1] Fair Play for Territorials. By Lieutenant-Colonel J. J. de Z. Marshall, V.D., R.A.M.C. (T.F.). Second edition. Gale and Polden, Aldershot; Clowes, Cockspur-street; Forster Groom, Charing Cross; or from the author, The Porch, Esher. Price 1*s.*

BRISTOL MEDICAL MEN *v.* BATH MEDICAL MEN AT GOLF.—The return match between representatives of the medical profession in Bristol and Bath took place on Oct. 25th at Sham Castle Club, Bath. An enjoyable game resulted in favour of the former team by 6½ points to 5½

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—In your last issue a writer says that he has never seen any letter showing why a system of payment for work done is impracticable. May I be allowed to point out two good reasons why it is improbable that any system other than payment *per capita* will ever be adopted generally?

1. In payment by the State for work done the present check on too frequent visiting would be abolished; on the contrary, the evil would be enormously stimulated. The patient, knowing that no doctor's bill would have to be met later by him, would encourage the medical man to come as often as possible, as such a cheery companion would greatly relieve not only his mental stress but also lighten the dull tedium of an illness.
2. There would be no reason why Hodge should not receive as much attention as Lady Vere de Vere, and, if given, that attention would have to be paid for; any doctor, therefore, who happened to find his banking account in an unhealthy condition could easily improve its tone by judiciously devoting a little extra care and attention to Hodge. And Hodge would not object were the State footing the Bill.

With such powerful inducements acting on both patient and doctor any funds available for payment for medical services would soon be exhausted, and it would be extremely difficult to provide any system of checking that would meet the difficulty.

There is one matter that seems to have escaped attention by any writer hitherto—viz., that if this Bill proves the blessing we all hope it will, it may eventually come about that the profession would actually be much worse off under a system of payment for work done than it would be under the contract system, owing to the race becoming so much healthier.

I thoroughly agree with Dr. B. Hall that if the capitation fee granted be adequate, medical practitioners will gain largely under the Bill. The evils attendant on contract practice can easily be removed in the manner I have previously pointed out.

I am, Sir, yours faithfully,

J. P. WALKER, M.D. Durh., D.P.H.,
Assistant County Medical Officer for Hampshire.

Winchester, Nov. 4th, 1911.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 28th the following sentence appears in an excellent letter from Dr. H. B. Luard: "This *per capita* system is fundamentally immoral, dishonest, and demoralising to both doctor *and patient*." Truer words have never been written since the foundation of the world. Now, Sir, I am delighted to hear that you deplore the extension of the contract system, and I note you say that, were it not for the fact that a majority of the profession has given adherence to the principle, you would even now consider it not too late to urge on your readers the danger of contract practice. Well, I do not know what is the proper definition of contract practice, but certainly a majority has not approved of payment by capitation; on the contrary, though there is a difference of opinion there is a distinct majority in favour of payment for work done. This being so, I implore you, even at the eleventh hour, to do all you can to help us in the matter. Nothing will tend more to raise and elevate the tone of the profession.

We want a lead. To say payment for work done is impossible is absurd. Only this morning a patient of mine said he felt certain that were a house-to-house canvass made and the opinion of the people to be insured ascertained they would be overwhelmingly in favour of paying the doctor for what he did—of course, because it would mean better attention and better work done, and this is what Mr. Lloyd George professes to desire, but he refuses to face the financial difficulty. It ought to be our business to force his hand and

to compel him to give us fair treatment—that is, payment for worth done. Much of the friction which is otherwise bound to occur between the profession and the Health Committees, embittering our lives and adding enormously to the difficulty of our work, could be thus avoided. We could at once agree, for example, to the £160 income limit.

I may say that this division of the British Medical Association (South Suffolk) has voted in favour of payment for work done.

I am, Sir, yours faithfully,

T. CUMING ASKIN.

Alderton, Woodbridge, Suffolk, Nov. 5th, 1911.

*** It has escaped Dr. Askin's attention that we have regularly deplored the extension of contract practice proposed under the Bill.—ED. L.

To the Editor of THE LANCET.

SIR,—An opportunity, which may never occur again, now presents itself to the medical profession—namely, the boycotting of all contract practice. It is inquisitorial and *infra dig.* My success in practice, some 40 years ago, dated from the day that I, as a provincial practitioner, and regardless of consequences, threw up all contract work.

I am, Sir, yours faithfully,

E. P. PHILPOTS, M.D. Aberd.

Constitutional Club, Northumberland-avenue, W.C., Nov. 3rd, 1911.

To the Editor of THE LANCET.

SIR,—I have been instructed by the Rossendale Medical Society to forward you the following resolution passed unanimously at a full meeting of the society on Nov. 1st:—

That this meeting of the Rossendale Medical Society reaffirms its absolute adherence to the six points of the policy propounded and placed before the profession by the British Medical Association, and pledges itself to use every means in its power to secure the enforcement of that policy.

I am, Sir, yours faithfully,

E. W. FALCONER, Hon. Sec.

Stacksteads, Bacup, Nov. 2nd, 1911.

To the Editor of THE LANCET.

SIR,—In the last issue of THE LANCET Dr. B. Hall sets forth very clearly his views in favour of payment *per capita* as opposed to payment per attendance. I do not think that contract practice such as obtains in public institutions, asylums, and the like can be brought into the comparison, as the conditions of service in these are so different. For instance, in his example of an asylum the inmates are all sick persons under treatment (mental, of course). If the medical officer were to be paid by capitation fee the "*capita*" would be the total number of persons in the area allotted to that asylum. Practically his only argument against the principle of payment by attendance is that it would necessitate an enormous amount of tiresome clerical work. All Government work means much clerical work, and under any system copious records will have to be kept. Doubtless under the payment by attendance system the clerical work will be more, but surely this would be preferable to the adoption of a system which enables a patient at no increased cost to himself or anyone (except the doctor) to call out a doctor at any time for any trivial matter. Dr. Hall must remember one thing—that under present conditions his contract patients pay nothing or pay voluntarily. Under the Bill they are compelled to pay, and therefore will naturally want their money's worth. Under the capitation system an insured person can have as much medicine and treatment as he likes without extra cost to the fund. Under the other system he will feel that he is drawing on the common fund which is in great part subscribed by his fellow workers, and therefore there will be some tendency for him to avoid unnecessary calls for attendance and medicine. I maintain that the payment-by-attendance system alone has the necessary basis of firmness, and that the profession should stand firm for that principle.

I am, Sir, yours faithfully,

Wisbech, Nov. 7th, 1911. M. TYLOR.

To the Editor of THE LANCET.

SIR,—You were good enough to print a letter from me in THE LANCET of Oct. 28th. Though hesitating to trespass further on your space I should like to reply to Mr. Benthall's remark in your issue of Nov. 4th, when he says that my estimate would mean an annual payment to the medical profession of over £15,000,000, and that he would "much like to know how it is proposed that such a sum could be raised." Exactly; that is just the point—the money cannot be raised. And because we cannot be properly paid Mr. Benthall's simple solution of the problem is that we should be content to take some grossly inadequate sum. Now when we find people doing business on these lines we rightly suspect the quality of their goods, and I for one cannot imagine how anyone but a lunatic could expect a doctor to give him attendance and medicine for a year for the price of a pair of gloves or a dozen collars. All would welcome a real solution of the problem of good medical attendance for everyone, but a scheme condemned by the profession upon which its working depends can only end in failure.

I am, Sir, yours faithfully,

London, S.W., Nov. 6th, 1911. EDWIN SMITH.

To the Editor of THE LANCET.

SIR,—Few medical men are fond of dispensing, neither is it, strictly speaking, their work; nevertheless, I think that the only conditions upon which medical men should allow the dispensing of medicines to be taken out of their hands under a National Insurance Bill are:—

1. That pharmacists are penalised for unqualified practice—e.g., counter prescribing; the unskilful or any tinkering with minor surgical wounds, beyond first-aid in case of emergency only; and the giving of any sort of advice or treatment for symptoms which patients in their ignorance are apt to describe to them upon entering their shops, &c.

2. That those pharmacists who undertake dispensing under the National Insurance Bill shall be prohibited from selling any patent medicines (this to include any proprietary medicine which does not bear legibly printed upon its label its exact composition) or abortifacients of any sort which are now asked for over the counter and sold as "female pills," "diachylon," "hiera picra," &c.

3. That the pharmacists under the Bill shall not be allowed to repeat any prescription without a written order from the medical man instructing him to do so.

I am, Sir, yours faithfully,

Birmingham, Nov. 5th, 1911. ERNEST C. HADLEY.

LEISHMANIA AND MOSQUITOES.

To the Editor of THE LANCET.

SIR,—My attention has been called to the interesting note by Professor Franchini on the development of leishmania donovani in anopheles. Professor Franchini infected his mosquitoes by causing them to feed upon artificial cultures of the organism. He found that the various forms persisted in the gut of the mosquitoes and ultimately terminated in the production of certain small forms of the parasite.

In my reports upon oriental sore in Bagdad, which have appeared in the "Report of the Advisory Committee for Tropical Disease Research Fund" (February, 1911), the *Journal of Tropical Medicine and Hygiene* (April 1st, 1911), and the *Journal of Parasitology* (October, 1911), I have given an account of experiments conducted with leishmania and mosquitoes. I found that stegomyia fasciata would feed readily upon the non-ulcerating form of oriental sore, and that in so doing it took into its gut numbers of leishmania tropica. In the intestine of the mosquitoes the parasites underwent a development into flagellate and other forms which have been described and figured in my report in the last number of the *Journal of Parasitology*. In view of my findings the results of Professor Franchini are very interesting. I have pointed out that the leishmania tropica undergoes a similar development in the gut of the bed bug of Bagdad, and owing to the fact that for reasons of distribution the bed bug cannot possibly be the natural intermediate host of the leishmania of oriental sore in Bagdad, I have been driven to the conclusion that the parasite of oriental sore develops in the intestine of the bed bug in just the same way as in artificial cultures in various blood-containing media. In connexion with Patton's discovery of the development of leishmania donovani in the bed bug, Mesnil has made the same suggestion, so that such a development does not necessarily mean that the insect in question is the natural host of the parasite. It is highly

probable that the parasites of the group leishmania will develop to a certain extent in the intestines of many insects, provided that they find there a suitable pabulum rich in blood. The development I have described of leishmania tropica in stegomyia fasciata, and that of leishmania donovani in anopheles by Professor Franchini, may be of this nature, and only, so to speak, accidental, owing to the rich nutrient fluid taken up with the parasites by these blood-sucking flies. I failed to infect myself with oriental sore by means of the bites of stegomyia fasciata previously fed on oriental sore, so I have no evidence that the development in the mosquito is a natural one. Conclusions can only be drawn when we know, not only that the leishmania develops into flagellates and other forms in any insect's gut, but that this insect also is able to transmit the infection to healthy animals as a result of transmission experiments.

I am, Sir, yours faithfully,

C. M. WENYON,

Protozoologist to the London School of Tropical Medicine.

Nov. 6th, 1911.

THE ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—I shall be greatly obliged if you will grant me the courtesy of your columns to express my thanks to the registered medical practitioners of Scotland for the great honour they have done me in re-electing me, without a contest, their representative on the General Medical Council.

I am, Sir, yours faithfully,

Nov. 7th, 1911. NORMAN WALKER.

To the Editor of THE LANCET.

SIR,—On Tuesday, Nov. 7th, a voting paper was posted to every registered medical practitioner with a registered address in England or Wales. Any practitioner who has not received a voting paper, *whether he wishes to take part in the election or not*, should immediately communicate with this office in order to make sure that his address is correctly registered and to prevent any risk of his name being taken off the Register under the following Section of the Medical Act:—

XIV. It shall be the duty of the Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the Orders and Regulations of the General Council, and to erase the names of all registered persons who shall have died, and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under this Act; and to enable the respective Registrars duly to fulfil the duties imposed upon them it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter it shall be lawful to erase the name of such person from the Register; provided always that the same may be restored by direction of the General Council should they think fit to make an order to that effect.

The importance of keeping open a channel of communication with this office cannot be too strongly insisted upon. All communications should be addressed to the acting registrar and not to any individual by name.

I am, Sir, yours faithfully,

NORMAN C. KING,

Acting Registrar, General Council of Medical Education and Registration of the United Kingdom.

299, Oxford-street, London, W., Nov. 4th, 1911.

THE LUNACY COMMISSION.

To the Editor of THE LANCET.

SIR,—I was very glad to see the sensible leader in your impression of Oct. 28th on the Lunacy Commission. Year after year I spoke and moved on this subject in the House of Commons, advocating the abolition of the perfectly useless legal commissioners and a large strengthening of the medical element, basing my arguments on the analogy of Scotland, where the Lunacy Board works well and commands public support. But, as usual, nothing was done. We are a long-suffering people, and our rulers are slow to move.

I am, Sir, yours faithfully,

Nov. 5th, 1911. ROBERT FARQUHARSON, P.C., M.D. Edin.

THE STRIKE AND THE DEATH-RATE IN LIVERPOOL.

To the Editor of THE LANCET.

SIR,—Professor Benjamin Moore, of the Liverpool University, in the lay press as well as in THE LANCET of Nov. 4th, endeavours to prove that the recent great strikes in Liverpool did not increase the death-rate, especially that due to epidemic diarrhœa among children. He concludes by indicating that a general strike of medical men may become a necessity and that we ought to have some meed of sympathy for men striking to obtain a living wage.

Surely it is quite obvious that persons who do not obtain a living wage cannot be expected to live wholesome lives. To talk of progress in sanitation while maintaining that widespread insufficiency of food, coupled with occasional absolute starvation, is a righteous state of affairs would be but a cruel manifestation of heartless hypocrisy. It is, on the contrary, from the ranks of the medical profession, and especially of sanitary reformers, that the best arguments have been produced setting forth the necessity, from every point of view, of sufficient food, of wholesome and appropriate food, combined with good housing and warm clothes. To enable everyone to earn enough to live a healthy life is an ideal all must approve. The real point at issue is whether the strike and all the suffering it entailed, such as the interruption of the sanitary services, of visits paid by lady inspectors to the poorest houses where children had recently been born, and the special work of the scavengers in the worst slums, did have any effect on the death-rate. But Professor Moore only takes into consideration the question of garbage, and maintains that its presence "in the streets has no effect on the epidemic." In a letter addressed to the *Liverpool Daily Post and Mercury* of Oct. 24th Professor Moore makes the following statement:—

It has long been a moot point amongst sanitarians and bacteriologists as to whether epidemic diarrhœa can be carried by ordinary garbage or whether it is carried by some direct agency from the dejecta of one afflicted individual to the food of another.

This was precisely the point raised, for after stating that though household refuse accumulated in the better parts of the town no harm resulted, I pointed out that in the slums, on the contrary, "adults sometimes do not take the trouble to go to the closets, and children habitually do all they need in the open air." This, then, is not ordinary garbage, but dejecta that may come from the afflicted and spread infection to the food of others. And it is because this very special danger is created daily in these localities that they are washed out with the fire-hose once or twice in the 24 hours. To stop so essentially necessary a service is to act in antagonism to the claim for a living wage. When the poor relief medical staff at Amiens went on strike, they did not let the patients die. They continued to attend to the sick but refused to be paid.[1] If the labour movement in Liverpool had been better organised it would, as a matter of policy as well as of humanity, have insisted on carrying out the indispensable sanitary services. Professor Moore, however, seems to think that these sanitary services are not much use in Liverpool because there was also a heavy epidemic in Dublin during August and September. But unless widespread and recent improvements have taken place in Dublin the very same cause of infection exists there as that which the special slum scavenger service removes from Liverpool, except when prevented by the strikes. In Dublin the grievance is even worse, for there are a large number of tenement houses, some close to College Green and the fashionable centres, where the street door remains ajar all night. The consequence is that strangers enter these houses, and the hall passage and stairs are often polluted with human dejecta. But at Liverpool hopes were entertained that the exceptional prevalence of infantile diarrhœa and other diseases would decrease in response to especially energetic sanitary measures. A particularly hot summer occurred when the efficacy of these precautions might have been tested, but now it is difficult to say how far the increased death-rate was due to the high temperature or to the disorganisation of the sanitary services. Other years have shown that epidemic diarrhœa is steadily diminishing, but the great heat of this summer would have been a supreme test. We might have better appreciated the good done by

[1] THE LANCET, March 7th, 1908, p. 747.

the spending of vast sums to provide dwellings for the poor, to utilise Liverpool's abundant water-supply in washing the streets, courts, alleys, passages, &c., to clear away the ashpits, to prevent garbage and refuse accumulating, to provide a large trained staff of female inspectors, and to instruct verbally and by placards and leaflets how infants must be fed and nursed. Much has also been done to provide "humanised" milk for infants and hospital accommodation for cases of infantile diarrhœa. By this improved municipal cleanliness and assistance in housing and feeding the poor, zymotic diseases in general have been steadily declining. The city is cleaner, the parents are better instructed, the houses of the poor are more frequently visited, infant mortality is no longer so frequent, and the population is better armed to resist the effect of excessive heat and dryness. Surely these are all good measures, not only in regard to the preservation of public health, but also from the economic and social reform point of view. But Professor Moore says in the *Liverpool Mercury* of Oct. 19th last that "there is not a shred of proof that the preventive efforts in the last two or three years possess any causal relationship with the decrease previous to this summer, or that the strike was connected with this summer's increase."

Thus, in the vain effort to show that the strike did no harm to public health we are invited to believe that sanitary measures can do no good. In reply I would submit that this is not the sort of advocacy which will strengthen the hands of those who claim for all the right to a living wage. On the contrary, as the poorer sections of the community improve their position and acquire increasing political power, they and their advocates should show an ever-increasing appreciation of the interests of the community as a whole, which sanitary science defends in the most practical and beneficent manner.

I am, Sir, yours faithfully,

THE LANCET SPECIAL SANITARY COMMISSIONER.

Nov. 6th, 1911.

OLD AND NEW VIEWS ON THE TREATMENT OF CONSUMPTION.

To the Editor of THE LANCET.

SIR,—I venture to suggest that Dr. C. Theodore Williams's Harveian Oration, published in THE LANCET of Oct. 21st, presents certain features which ought not to pass unchallenged, more especially as Dr. Williams is a recognised authority on consumption, and as one of the points on which I dare to differ from him is of vital importance to the treatment of consumption in England.

Dr. Williams writes of acute cases of phthisis that they "all pass through an early stage to a fatal issue." Further on he writes: "It is true in some of these cases the disintegrating process comes to a standstill and fibrosis sets in—the disease is incapable of cure." In other words, they all die early; but some don't! Probably every sanatorium doctor with a few years' experience has seen one or more of these patients with acute disease recover health and return to a full day's work. No doubt these are cases of arrested, not cured, disease; but, after all, more cannot be said for any other form of phthisis, however early the patient may have come under proper treatment, and however vigorous and fit for work he may have become.

It is surely an old and almost discarded rather than a new and accepted view that mountain climates have a remarkable effect on phthisis. Doubtless certain patients do better in high altitudes than in the lowlands, but the reverse is also frequently the case even when there is no cardiac complication. The number of recent observations which go to show that there is no such thing as a specific climate for phthisis is great, and I will confine myself to the more recent. Dr. Kaurin has published in the July number of *Medicinsk Revue* this year a comparison of the results obtained at 11 different Scandinavian and Finnish sanatoriums, the height of which above the sea varied from 11 to 470 metres. There was a striking similarity in the percentage of cases which each sanatorium discharged improved, but the best results were obtained at Vejlefjord sanatorium, which is only 25 metres above the sea, and where only 13 per cent. of the patients were in the first stage of the disease. Dr. Ost has collected the reports from eight Swiss sanatoriums, 907 to 1860 metres above the sea, and the total percentage of cases discharged improved is lower than that at Vejlefjord sanatorium. When the leper hospital at Reknes on the west coast of Norway was converted into a sanatorium in 1897 much hostile criticism was provoked because of the climate, which is changeable and windy, and because the sanatorium is only a few feet above the sea. Experience has shown, however, that the results obtained at this sanatorium are quite up to the average of high, inland sanatoriums.

Dr. Williams writes: "Of all my statistics of consumptive patients, the high altitude cases yielded the most favourable results, and, what is most important, showed the fewest relapses." Quite so; but it is usually only those who are rich enough and well enough to travel afar who ever reach the high altitudes, while the less fortunate cases remain in England. A comparison, therefore, between the rich and relatively strong patients who recover in Switzerland with the poor patients whose disease has been recognised late and treated at home is open to criticism. Last year I worked in a private sanatorium in the south of England where a restless spirit existed among some of the patients because their London doctors had taught them that their present treatment was but preliminary to a complete cure in Switzerland, to which they should travel as soon as they were strong enough. I hold no brief for English sanatoriums, but it strikes me that the "high altitude" teaching is unfair on them and on many patients who either spend money beyond their means in travelling abroad, or remain at home under the impression that their chances of recovery are relatively small. It is superfluous to point out how detrimental to the growth of working-class sanatoriums in England this "high altitude" teaching is.

Dr. Williams completely ignores the modern surgical treatment of phthisis. Doubtless he has seen fit to exclude from his oration all new methods of insignificant or ephemeral value, but surely these terms are inapplicable to the works of Forlanini, Murphy, Brauer, Saugman, and Freund during the last two decades? The treatment of phthisis by artificial pneumothorax, for example, is now adopted in suitable cases in the leading continental sanatoriums as a matter of routine, and it is considered as orthodox as the surgical treatment of appendicitis. In one large continental sanatorium one third of the patients have simultaneously undergone this treatment which has arrested many cases of severe disease.

I am, Sir, yours faithfully,

Gorleston-on-Sea, Oct. 30th, 1911. CLAUDE LILLINGSTON.

THE RELATION OF THE ORGANIC PHOSPHORUS CONTENT OF VARIOUS DIETS TO DISEASES OF NUTRITION, PARTICULARLY BERI-BERI.

To the Editor of THE LANCET.

SIR,—With reference to Professor B. Moore's letter in THE LANCET of Oct. 28th, the annotation in THE LANCET of Oct. 14th emphasised the importance of phosphorus. The work carried out in the Institute for Medical Research had shown that deficiency of phosphorus was not the cause of beri-beri; I considered it necessary to direct attention to this point, and thus prevent further work being expended in unprofitable research. As regards Professor Moore's statement that the active substance is probably a glucoside I might direct his attention to the fact that the protective fluid employed by us did not yield more glucose after than before inversion; the estimations were made gravimetrically by one of our chemists.

I am, Sir, yours faithfully,

H. FRASER,
Director, Institute for Medical Research,
Kuala Lumpur, F.M.S.

Nov. 2nd, 1911.

FEES TO SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—I am very pleased to see by THE LANCET of Nov. 4th that the Peninsular and Oriental Steamship Company has fallen into line as to allowing ship surgeons to charge reasonable fees for treatment of first- and second-class passengers. It is now about six years since I put my proposal to the above effect before one of

the managers of the White Star Line, and to this line is due all the credit of crystallising my suggestion into actual shape. Since then the Cunard, American, Dominion, Leyland, Allen, C.P.R., and Booth Lines have agreed. In London the Orient Line has followed. It would be a great help if the present and past surgeons of the Pacific Steam Navigation Company petitioned the manager of that line to agree. May I just suggest that a few surgeons are helping to ruin my proposal by objecting to submit their bills to the captain of the ship. I quite agree to the right of the companies to do so. Perhaps it would give better results if each ship's surgeon and intending surgeon bought a copy of Styrap's "Medico-Chirurgical Tariffs" (H. K. Lewis. London. 2*s.* 6*d.*) and be guided by the scale of fees under class 1 and 2 for first- and second-class fees. Otherwise the steamship companies may do so. If the above rearrangement has been and will be the means of adding a few thousands to a badly paid branch of medical practice I shall be glad.

Just one more point; although I meet, now and then, ship surgeons I am glad to say that not one of them has ever said "Thank you" for the work I have done for them. I have always contended that the person who invented the word "gratitude" in relation to medicals should have been shot!

I am, Sir, yours faithfully,

Liverpool, Nov. 5th, 1911. R. R. RENTOUL.

*** Medical men probably have not recognised in Dr. Rentoul the originator of the reform movement.—ED. L.

TRANSMISSION OF DISEASE BY MEANS OF BOOKS.

To the Editor of THE LANCET.

SIR,—I am preparing a paper upon "Books a Source of Disease," to be read before the next International Congress of Hygiene, and in order to obtain data respectfully request the readers of this note to send me an account of any cases the source of which has been traced to books or papers, or where the evidence seemed to make books or papers the offender. I would also further request information where illness or even death has been caused by the poisons used in book-making.

All the information possible is wanted to present as complete a paper as possible. As in the case of insects which we now know to be "carriers of disease," it is first necessary to collect the scattered evidence in order to show that there is real danger in books; and this will compel better care to be taken of libraries and books and improve the health of mankind. I am, Sir, yours faithfully,

WM. R. REINICK,
Chief of the Free Library of Philadelphia.

1709, Wallace-street, Philadelphia, Pa., Oct. 26th, 1911.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, THE MEDICAL DEFENCE UNION, AND THE ACTIONS OF PARTNERS OR ASSISTANTS OF THEIR MEMBERS.

To the Editor of THE LANCET.

SIR,—Owing to certain misunderstandings which have arisen from time to time as to the scope of the work of the London and Counties Medical Protection Society and of the Medical Defence Union in respect of members in actions brought, or sought to be brought, for alleged negligence, we are directed by our respective councils to state officially that membership being purely personal no action arising solely out of any act of a partner, assistant, or locum tenens can be taken up unless the partner, assistant, or locum tenens is also a member of either the Medical Defence Union or the London and Counties Medical Protection Society. It is hoped that a time will soon come when all registered practitioners, whether principals or assistants, will secure the advantages pertaining to membership of one or other of these societies as a matter of course as soon as they become qualified. We are, Sir, yours faithfully,

HUGH WOODS, M.D.,
Gen. Sec. London and Counties Medical Protection Society, Ltd.
A. GEORGE BATEMAN, M.B.,
Nov. 6th, 1911. Gen. Sec. Medical Defence Union, Ltd.

TORSION OF THE FUNIS AS A CAUSE OF DEATH OF THE FŒTUS.

To the Editor of THE LANCET.

SIR,—In reference to Mr. H. A. Lediard's article in THE LANCET of Oct. 28th on Torsion of the Funis as a Cause of Death of Twins, I might mention a case which was under me about ten months ago. It was also a case of twins, but born at full term. The first to be born was a female, weight 6¼ lb., and a vertex presentation; then the second child, a male of about six months' development, was born as a breech presentation in the membranes almost immediately after; then finally the placenta of the first child came. The cord of the dead fœtus was twisted at the umbilicus and was here little larger than the lead of a pencil. It resembled very closely the twist in the cord of the smaller fœtus shown in Mr. Lediard's photograph. The fœtus did not show advanced decomposition. The skin was peeling and the scalp was loose, but there was no discolouration. I do not see how the appearance of the cord could have been consistent with the twist having occurred after the death of the fœtus, and I looked upon the former as the cause and the latter the effect. The living twin was quite healthy and weighed 8 lb. 12 oz. when a month old. The woman's next youngest child, aged 2 years, was a fat, rosy, very healthy-looking child, and there was no history of miscarriages.

I am, Sir, yours faithfully,

IDA C. TENGELY.

The Union Hospital, Bradford, Nov. 6th, 1911.

THE RECENT MILITARY TRAINING ON SALISBURY PLAIN.

(FROM A SPECIAL CORRESPONDENT.)

DURING the past summer and autumn months a large number of troops—regulars, special reservists, territorials, and yeomanry—were concentrated for their annual training at the various camping grounds on Salisbury Plain. Owing to scarcity of water and other unforeseen reasons the inter-divisional and army manœuvres had to be abandoned, but the individual training of units of all arms, as well as brigade training, was carried out in a thorough manner under very favourable conditions as regards the weather, and taken as a whole the troops benefited very considerably from the change of air under canvas. The health of all ranks during the period they spent under canvas was exceptionally good, and the military efficiency was certainly increased.

Medical and Hospital Arrangements.

Each regimental unit had a commissioned medical officer appointed to look after the sanitation of the camp and to deal with casualties and cases of sickness. These officers were also entrusted with the training of the regimental stretcher-bearers and regimental sanitary squads in the various duties that these men would have to undertake in time of war. An observation hospital was established at each encampment for the treatment of minor cases of illness that occurred, and the sick were provided with accommodation prior to their transfer to the regular military hospitals established at Bulford Camp and Tidworth Park, Salisbury Plain. Officers of the Royal Army Medical Corps were instructed on arrival to report when assuming charge of any camp to the administrative medical officer of the Tidworth District, and at the same time to state that their equipment was in accordance with the scheduled list laid down. They were also directed to report to the officer commanding each unit as it arrived in camp and to assist him in reference to carrying out the sanitary regulations as noted in standing orders for Salisbury Plain.

The treatment of serious cases, except under circumstances of emergency, was not to be undertaken in the observation hospitals, as these cases were to be transferred to the permanent hospitals at Bulford and Tidworth Park. An infectious disease isolation hospital was placed at Brimstone Bottom and telephonic communication was established with this from each of the military encampments. Ambulance wagons were stationed at each camp for the purpose of transferring the sick to the receiving hospitals, and other ambulance wagons were detailed to accompany the troops

on field days, or when necessary. Notice by telephone was ordered to be sent to the receiving hospital whenever it was intended to transfer sick, the number of cases being despatched and their probable hour of arrival being notified. When possible all sick were to be transferred before noon daily. If from any cause an ambulance wagon was not available in camp, one was to be requisitioned for from the receiving hospital. In each camp hospital a small supply of medical comforts, such as extract of meat, condensed milk, arrowroot, and stimulants, was provided for emergency. Field medical and surgical panniers, containing medicines, appliances, and a complete set of surgical instruments, were issued for the treatment of men reporting sick and for such casualties as might occur. Replenishment when necessary was obtainable on requisition from the officer in charge of the receiving hospital.

The continuous treatment by the intramuscular injection of mercurial cream of cases of syphilis was not lost sight of, as the case-sheets of any men suffering from this disease were forwarded to the medical officer in charge of the unit to which the men belonged. Syringes, "all glass," were issued to each camp hospital and the necessary medicaments were obtainable from the receiving hospital of the camp concerned. This was a very necessary proceeding, for it is of the utmost importance that these cases should not have any interruption in their course of treatment as might otherwise occur when troops are absent from their regular stations. All cases of soldiers attending or receiving treatment in the camp hospitals for any ailment had an entry made in the "admission and discharge book" of the hospital for statistical and other purposes, and a compilation of these returns was made out monthly by each camp hospital, and sent to the officer in charge of the receiving hospital.

Sanitary Duties.

Orders were issued for a weekly health inspection of all troops and details in each camp, the hour for this inspection to be arranged by each medical officer in direct communication with officers commanding units. A sanitary inspection was invariably also made on the day following the arrival of each corps or unit in any encampment. Besides the inspection of the troops frequent sanitary inspections of the camps and their surroundings were made and any defects noted in the "Sanitary Diary" and immediately brought to notice of the commanding officer of the unit concerned. Notes of any recommendations or suggestions, with results, were also included in the weekly sanitary report forwarded by the senior medical officer of each camp to the administrative medical officer of the Tidworth District, who was the chief military medical officer of Salisbury Plain.

Medical officers in charge of the various camp observation hospitals had to arrange for the sanitary squads of units in their camping area to parade once a week for a lecture on camp sanitation. In addition to this the squads were taken round the camp once a week by the medical officer personally, and were given a practical demonstration of the duties they were required to perform. These parades were arranged between the senior medical officer and the commandant of each camp.

Conservancy.

The most important matter of camp sanitation consisted in the conservancy arrangements for the collection, disposal, and disinfection of night soil (human excreta), horse litter, ashes, and rubbish, all of which were removed by contract by civilian labour from the camps daily, and deposited at some distance from the War Department area (not less than half a mile) as agreed upon, in properly constructed carts, in such a manner to satisfy the War Department authorities that no danger to health or public nuisance could arise therefrom. The latrines were all on the pail system, with finely powdered earth to be used as a deodorant. Each pail was emptied in the early hours of the morning and then wiped over, inside and out, with kerosene oil as a deterrent to flies, and a small quantity of a 2½ per cent. cresol solution (liq. cresoli saponatus fortis 1½ oz. to 1 gallon of water) was placed in the interior of the bucket. The latrines had board seats and were partitioned off in single compartments for privacy, the whole being surrounded by a canvas screen. Separate pails were provided for use as receptacles for urine, these being similarly treated with kerosene oil and cresol solution, and also having some fresh chloride of lime placed in them. The floors of the latrines were sprinkled daily with kerosene oil and chloride of lime. The absence of flies under such strict sanitary conditions was very apparent and was the subject of remark by several distinguished sanitarians who visited the camps.

The cook-houses were supplied with tubs, having tight-fitting lids ("swill-tubs") for the collection of greasy water and food refuse; these were also emptied and cleaned out daily by civilian contract. Separate areas were fenced off and notice boards put up to mark them for "ashes," "rubbish," and "horse litter," and separate properly covered carts for each of these went round the camps daily and removed them. Particular attention was paid by the medical officers of each unit that the sanitary condition of the latrines, urinals, cook-houses, lavatories, and refuse areas, was efficiently maintained, and for this purpose they paid continual inspections to these places.

Tents, Water, and Rations.

The sanitary conditions of the men's tents also received particular attention. Tent flies were looped up first thing each morning; in wet weather they were, however, looped up only on the leeward side. In all standing camps the tents were struck periodically, and the ground underneath well swept and left exposed for some hours to the sun, the tents being eventually replaced on their former sites. Tents were never pitched for occupation in the intervals. Where tent bottoms were used they were removed every other day when possible, and the ground beneath thoroughly cleansed. As a rule, however, it was found that the regular troops much preferred the bare ground to tent boards, as they were able to accommodate themselves better on "mother earth" than upon the more rigid boards, which they considered cold from the circulation of air underneath. One blanket was issued to each man as a general rule, but in some units two per head were found advisable.

Filter-water carts were taken by each unit, as where water from any doubtful or untested source had to be used for drinking purposes it was directed that the filter-water cart should invariably be used. Each unit had a special *personnel* told off for water duties; each battalion of infantry, for instance, provided one non-commissioned officer and four privates. Two privates from the Royal Army Medical Corps were detailed for all other duties, to which they were attached for rations and tentage. Rations were all that could be desired, fresh meat and bread being issued daily, except on one day a week when corned beef ("bully") in tins and biscuit were served out. Fresh green vegetables, potatoes, onions, &c., were purchased from the regimental institutes by the company messes out of the men's messing allowance. Messrs. Dickeson had most of the arrangements for the canteens, coffee-rooms, and regimental institutes, and did everything possible to make the men comfortable.

General Remarks.

It was apparent that all branches of the regular army were in a high state of efficiency. Their physical and medical condition has never been better. The special reservists show an improvement on last year and will continue to improve as the old militia men get "weeded out." No remarks can be offered concerning the army reservists, as no members of this branch of the service were called upon to undergo training. It was noted that the new web-equipment was in use by all infantry units and was well reported on. It is, however, regrettable to observe that the Royal Army Medical Corps are still marched out in the old pattern fatiguing equipment with all its array of pipeclay and unyielding straps. During the heavy rains that occurred at some periods of the training the poor quality of the material in the men's greatcoats became very apparent; the cavalry cloaks also appear to be absolutely worthless as far as their waterproof quality is concerned. The old pattern blue Melton cavalry cloak was a great boon to the mounted soldier, as was the dark infantry greatcoat. The khaki-coloured field service cloth now used in the manufacture of these garments is not only not waterproof but soaks up all moisture and rain and becomes unbearably heavy to the wearer as a consequence. The weight of kit allowed for each soldier on manœuvres and training also appears to be on the meagre side, as it does not allow in all cases of sufficient change of flannel shirt, underclothing, and socks to be included. In some units it was noticeable that the men not having brought a change of the regulation

flannel shirts had to resort to purchase of cotton shirts, and some even restricted themselves to wearing gauze vests under their jackets. During the cold nights chill to the abdominal organs resulted, and diarrhœa and colic often followed as a direct consequence.

All ranks appeared to appreciate their life under canvas—by no means an easy one, as *reveillé* sounded daily at 5 A.M. and the marches were often long and fatiguing. No complaints were heard, and the only drawback that seemed to strike the onlooker was the pity that this fine fighting machine of ours, the pick of our youth, living under the best possible conditions for health and vigour, was so small numerically.

THE DEMAND FOR PUBLIC ABATTOIRS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

SLAUGHTER-HOUSE SCANDAL AT NEWCASTLE.

One of the Largest Centres of the Cattle Trade.

NO one with knowledge of sanitary questions denies that there is urgent need of extensive reforms in Newcastle. On the other hand, public opinion has not yet been educated to the point of understanding that at least one requirement, and this among the most pressing, can be obtained in such a manner as to produce revenue instead of augmenting the rates. Though there has been a great falling off in the sale of cattle during the last 20 years the Newcastle Cattle Market still occupies the position of the second greatest fat-cattle market in the Kingdom. In 1889 there were 125,791 cattle, 9053 calves, 325,030 sheep, and 40,930 swine exposed for sale on this market. Twenty years later, in 1909, the figures were 86,729 cattle, 6203 calves, 316,273 sheep, and 30,621 swine. This does not mean, however, a falling off of the food-supply. In 1889, of the cattle brought to market no less than 76,682 came from abroad. The majority, 36,000, came from Denmark and the rest from the United States, Canada, Norway, and Sweden. In 1892, however, the importation of cattle from Scandinavia was prohibited, and Canadian cattle had to be slaughtered immediately on landing. These restrictions are still in force. But there are now large ships with cold storage plant carefully installed that bring the carcasses instead of the live cattle. The food-supply has not decreased, only it comes in a different form. It is to be presumed that the measures taken to prevent the landing of live cattle will be removed when there is no longer any danger of importing cattle disease.

Of the 86,729 cattle brought to the Newcastle market only 19,682 were actually slaughtered in the town, together with 99,476 sheep, 3444 calves, and 13,144 swine. Thus by far the greater number are slaughtered elsewhere. Nevertheless, the slaughtering that is done at Newcastle is sufficient to provide good revenues to the town. If we count in round figures 20,000 horned cattle at 3*s.* each, that would be £3000; 100,000 sheep at 6*d.* would yield £2500; 3444 calves at a little more than 1*s.* would make £200; and 13,144 swine, including payment for the removal of the bristles, another £2300; altogether probably £8000 annual income, not to mention the great profits that must be made on the by-products. With such security a loan could be obtained. It may be objected that this means the establishment of a municipal abattoir; but if this be an objection, it cannot hold good at Newcastle, for there already exists a public abattoir which is the property of the corporation. Unfortunately it is antiquated. But by far the greatest difficulty is to deal with the numerous private slaughter-houses that have been allowed to remain. Some of these I visited, and they made me feel truly sorry for the inhabitants of Newcastle.

A Miserable Municipal Abattoir.

Some three years ago there were 132 licensed slaughter-houses in the city and county of Newcastle. It was openly acknowledged that these places were very generally quite unfit for the purpose. The veterinary officer and the meat inspectors all declared that the private slaughter-houses were so distant one from the other that anything like efficient inspection was impossible. The sanitary committee then refused to renew the licences of some of the worst places. Five groups of slaughter-houses were arranged, but 14 individual slaughter-houses scattered in different directions were still allowed to exist. One of the five groups, consisting of 40 slaughter-houses, was subsequently condemned because the owners would not carry out the improvements judged to be necessary. Nevertheless the licence was renewed for short periods, the fact being that, though there is a municipal abattoir, it is so small and so little in keeping with the requirements of the age, that the authorities could not easily compel butchers to go there. This building, such as it is, has at least the advantage of being side by side with the cattle market, but it is not nearly large enough. Then it is built on the wrong principle. Instead of consisting of one or more large slaughter halls with lofty roofs and air and light streaming in from all sides, it is divided up into little slaughter-houses measuring 16 ft. by 14 ft. 6 in., which are let out to individual butchers. To each of these small slaughter-pens a pen is attached of the same size. Thus both the animals that are to be killed and the methods of killing are kept private and within the four walls of these small premises. The inspector, it is true, has the right of entry, but he cannot constantly run in and out of small compartments. One of the great advantages of a slaughter-hall is that it destroys this fatal ideal of privacy. The preparing of the people's food is a public service, and there ought not to be a vestige of privacy allowed.

Certainly these small municipal slaughter-houses have nice glazed tiles up to the height of six feet. Natural ventilation is provided higher up and is good as far as it goes, but the whole arrangement is wrong. Sometimes two or three butchers club together to hire one of these small slaughter-houses, and when they all work at the same moment there is not enough room for them. In this small space, 16 ft. by 14½ ft., as many as 20 to 30 sheep and three or four big cattle will be killed in one day. Then there are no premises for the treatment of the by-products or facilities for the prompt removal of the meat to a cooling room so that it may set properly. The pen also is only separated from the slaughter-house by a door, which is often allowed to remain open. The poor animals thus obtain a near view of the slaughtering and the cutting up of their fellow creatures while they are waiting to meet their doom. This is certainly cruel and ought not to be allowed. At the end of the row of these diminutive slaughter-houses there is a somewhat larger slaughter-house which is not rented to any particular butcher but is open to all on the payment of a small sum for each animal killed. The charge is only 1*s.* for horned cattle, 6*d.* for calves, and 2*d.* for sheep. Of course, a much higher charge could be made in a public modern abattoir. Nor would such a higher charge justify an increase in the sale price of meat, because it represents but a small sum on the total value of the meat, and the butcher, having no more rent to pay or expenses to incur for the upkeep of his private slaughter-house, can very well pay the higher fees out of this saving. Close by the slaughter-house there is a shed for the sale of meat by auction. This structure is narrow and low, and at the moment of my visit a sheep had been killed there, in spite of the quantity of meat hanging up for sale close to the bleeding animal. This is an example of the carelessness, the indifference to modern principles that prevail even on the municipal property.

Maggots for Dripping and Margarine.

What, then, must be the state of affairs in the private slaughter-houses? What I saw was terrible enough, and yet the inspectors in their official reports tell an even more repulsive story. The best that can be said about a group of private slaughter-houses which I inspected is that the windows had iron rails across but no glass panes, so there was ventilation, and this in all weathers. But there was not much light, for the windows were high up and near the roof. A partition wall did not reach this roof, and on the other side there was another slaughter-house. Thus the air travelled over the top of these dark, noisome shambles. Yet outside and very close at hand there were many inhabited houses. Within one slaughter-house I found a very bad case of tuberculosis. The carcass was hanging from the ceiling, and underneath crouching in a dark corner were four living sheep and a poor frightened little calf. The walls were not of glazed tiles, but of porous brick that had merely been whitewashed. On the ground there was at least half a cartload of intestines, pouches, and filthy offal. A sort of cement is supposed to have been put between the stone pavement to

make it water-tight. The licence of this place expires in a month's time. It would be easy to close it by refusing to renew the licence, but where are the present occupants to go? Such slaughter-houses are a danger to the community; but though what I saw was bad enough, it did not come up to the following case given in his annual report for 1910 by the veterinary officer, Mr. Thomas Parker, F.R.C.V.S. :—

One afternoon, during July last, on entering slaughter-house premises within the city they were found in a filthy condition; dirty sacks and boxes containing old bones, fly-laden and filthy, were scattered about, and a refuse cart standing in the yard was simply overladen with filth. Part of these premises were used in which to prepare cooked meats. On entering the fat-mincing room a large bath was found containing 1 cwt. 104 lb. of intestinal and other fat improperly cleansed and literally alive with maggots. In a tin near the bath was found 1 cwt. 54 lb. of the same kind of fat, also alive with maggots. In another tin was found 1 cwt. 24 lb. of fat which had just been put through a machine-driven mincer, the maggots in this case having been ground up with the fat. Large maggots were crawling about the floor. According to the manager, it was intended to mince the whole lot, and then boil it down for dripping, to be sold for human consumption. The whole of the abominable filth was seized and destroyed, and as repeated warnings had not had the desired effect the proprietor of the establishment was summoned and fined £5 and costs.

It would appear as if some considerable number of persons in this trade had no objection to things putrid. The fat mentioned above is generally used for making margarine, though in this case it was destined for dripping in spite of the maggots it contained. It appears also the impression has gained ground that good sausage skins cannot be made unless the intestines used are in a state of putrefactive decomposition. It is then easier to scrape them. They are rubbed and mixed with coarse dry salt. Though this somewhat reduces the intensity of the stench it does not suffice to purify the skin. So general has the practice of using rotting intestines for sausage-skins become in Newcastle that the sanitary authority has found it necessary to issue a circular to all butchers and others concerned warning them that if any putrid sausage skins were found in their possession they would be seized as unsound food.

Newcastle's Golden Opportunity.

Of course, the preparation of sausage skins should be done only at a public abattoir. The utilisation, treatment or preparation of the blood, the hearts, livers, feet, calves' heads, tripe, &c., should equally be restricted to the premises, where there is always a veterinary surgeon on the spot, together with inspectors and other guardians of the interests and the health of the consumer. It must, therefore, be a large place with a numerous staff. Everything which should be properly controlled must be done there and nowhere else, and there must be specially constructed carts to convey the food in a perfectly protected manner from the abattoir to the retail depôts in different parts of the town. This can be done at Newcastle with greater facility than in most towns, for the initial difficulties are already to a large extent overcome. The first obstacle is inability on the part of the ratepayers to understand the question at issue and their objection to the principle of municipal enterprise. But here the principle is already conceded, a municipal abattoir exists, and it is no longer a question of doing something new, but of doing this in a better, a more profitable, and a more effective manner. Having obtained assent to the principle, the next obstacle generally encountered is to secure a suitable site for a price that will not be so high as to handicap the enterprise too heavily. This is the more difficult as the abattoir should be by the side of the cattle market, and both ought to connect with the railway system and whatever watercourse there may exist in the neighbourhood. Most fortunately, at Newcastle, the municipality already owns a large part of the district of Walker to the east of the city. Here the river Tyne and two railways go through the quarter. So there is every facility. The land is good and dry, and the only objection is the existence of coal mines underneath, so that there might be some subsidence of the soil. The mines, also, belong to the corporation, but have been let to a mining company. Some municipal property has already been damaged by a subsidence, and the question arises whether the town has a claim for damages on the mining company. However this may be, of all forms of municipal construction a cattle market and a public abattoir have the least to fear from a subsidence of the soil. It is preferable in both cases to avoid any heavy overhead structure. There should be no second floor and but slender roofs admitting the utmost light and air. With such structures there is not much danger of a serious catastrophe even if some subsidence of the soil does occur. Thus, there is a great opportunity for Newcastle to place itself on a level with the towns of the continent, especially of Germany. With Denmark the figures given above indicate there has been a large trade in meat, but Copenhagen has a profitable and model municipal slaughter-house. The last account at my disposal dates back to 1908–09. During that year the receipts at the Copenhagen municipal abattoir amounted to £35,460 and the expenditure to £30,565. Thus while the meat was prepared under safe and wholesome conditions, offering a sound guarantee to the public, the municipality was put to no cost, but, on the contrary, cleared a net profit during the year of £4895. Why should not Newcastle do likewise?

(To be continued.)

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

The General Infirmary: Reopening of a Block.

THE south-east block of the General Infirmary, which was opened in 1894 and which, it will be remembered, was in great part destroyed by fire some 12 months ago, was reopened by the Lord Mayor on Oct. 31st. After a short dedicatory service, conducted by the vicar of Leeds, the Lord Mayor, Mr. William Middlebrooke, M.P., in a few well-chosen remarks declared the block reopened. Mr. Charles Lupton, chairman of the weekly board, explained the scheme of reconstruction which the block had undergone. The meeting, which was a very large and representative one, afforded an opportunity for Lord Airedale, who proposed a vote of thanks to the Lord Mayor, to make his first speech in Leeds. He reminded the meeting that the foundation stone of the present infirmary, which was opened in 1868, was laid by his grandfather, emphasised the great interest which his father had always taken in the welfare of the infirmary, an interest to which earlier speakers had borne testimony, and assured the meeting that he would always do what he could to favour the development of the institution, which was one of the most useful in the city. The block, which was originally built separate from the main building, consisted of three storeys, each having a front and a back ward; these were separated from one another by the main staircase, access from which was obtained to entresol wards. The back wards have always been regarded with some disfavour as looking less cheerful and as getting less light than the other wards of the infirmary. In addition to this the access to the various wards was not good; a covered corridor on the ground floor was during the original construction of the block supplemented by a bridge on the first-floor level, while during recent years an improved access has been obtained to the second-floor wards from the terrace by the construction of a second bridge. The reconstruction scheme has done away with the central staircase; in this way the front and back wards have been thrown into one on each floor, the entresol wards have disappeared, and a new access has been obtained to the block on all the floors by extending it at the north end, so that it communicates directly with the main building. This extension provides accommodation for the staircase and the entresol wards. The fire which occurred last year, and which was happily not attended with injury to anyone, brought home to the members of the board certain defects in the construction of the roof of the various blocks of the infirmary, and in the reconstruction of the south-east block these have been borne in mind and precautions have been adopted in connexion with the rest of the building. It is hoped that the block will be in full working order this week.

King Edward Memorial Fund.

The fund which is being raised as a memorial to the late King Edward has now attained a total of £106,000. A meeting of the committee of the fund was held at the infirmary under the chairmanship of the Lord Mayor, who has acted as the president. At this meeting it was decided to hand over to the infirmary the sum of £50,000 in

order to meet the expenses of the reconstruction of the south-east block in so far as that was not covered by insurance, and to pay for the land which has been acquired for the extension of the buildings. The Lord Mayor, whose term of civic office expires in a few days, agreed to the strongly expressed wish of the meeting that he should continue to act as president of the fund until the full amount of £150,000 was obtained. As everyone knows, it is not the collection of the earlier thousands that is the main difficulty in appeals of this kind, for in a large community one can safely rely on the support of a good many people who subscribe to all good objects; the chief difficulty is met with in the endeavour to secure that their excellent example shall be followed by those who can afford the smaller sums which are so essential to the complete success of the appeal. In this connexion attention may be called to a letter in the local press from Mr. G. Lane Fox, pointing out to the inhabitants of his county the large amount of work that is done by the infirmary for patients who come from all parts of the West Riding, and in many cases from places which give a very small amount of pecuniary support to the institution. He calls on those who can afford to do so to increase their subsriptions, and gives the best of all examples by substantially increasing his own. It is to be hoped that this appeal will bear fruit. Mr. Lane Fox's letter touches very pertinently on an aspect of the work of the infirmary which has been frequently spoken of by Mr. Charles Lupton, the chairman of the board, and as recently as at the meeting held at Manchester of representatives of the provincial hospitals to consider the bearing of the Insurance Bill on the funds of the voluntary hospitals. As Mr. Lupton explained, a considerable amount of work is undertaken by the infirmary which could not be done at the smaller centres; the patients must be dealt with at institutions like the General Infirmary, and it would be with the utmost possible reluctance that any difficulties would be raised to the ready admission of cases from a distance provided always they were of a character which could not be dealt with at the smaller centres.

Nov. 7th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Schools for Crippled Children.

IN our large cities there are unfortunately, especially in industrial centres, a large number of cripples, many so handicapped that they are unable to attend the public elementary schools. Within a radius of three-quarters of a mile from the Manchester University Settlement in Ancoats there are 300 crippled children. The Santa Fina branch of this settlement has begun to do something for some of these unfortunates. In one of the rooms of the settlement there is a little daily class of 12 crippled children, ranging in ages from 5 to 8, a lady having undertaken their instruction on the Froebel system. Mrs. Humphry Ward gave an address to help the cause of cripple schools for children, and urged that Manchester should join hands with London in the foundation of its school. Manchester has a residential school, but it is desirable also to have a day cripple school, such as exists in Liverpool, Birmingham, and London. The first school for cripples in London was started in 1899, and the project flourished. The crippled children are brought to the school, for which purpose there are 45 ambulances and 40 horse omnibuses. They are brought at 9.30 by the nurse, who is responsible for their safety, with special helpers. They have an interval for play in the forenoon, at 12 they get dinner, and resume work at 1.30 until 3 o'clock, when the ambulances arrive and take every child home. In London there are now 39 day schools for the physically defective, with total accommodation for 2901 children. The average attendance of the children for the past year was 2237. The children remain in attendance at the school until they are 16, and there is abundant testimony to the good results of the early training in the after-life of these persons.

Salford Hospital Annual Meeting: Very Small Contributions by Working Men.

The annual meeting of the subscribers to the Salford Royal Hospital was held on Oct. 27th. The King Edward VII. Memorial Wing is now completed, and the hospital will now accommodate 209 beds, or 74 more than before the extension. Only 39 of the additional beds will be occupied in the first instance. These will increase the annual expenditure to £10,250, and the annual income is only £8200, so that unless new sources of income are obtained to the amount of £2050 a year the capital of the hospital will be reduced. In response to the appeal issued in June, 1907, for £70,000, nearly £60,000 have been received. The chairman remarked that if the Insurance Bill passed in its present form the hospitals in the country would suffer great loss. The total number of the in-patients, out-patients, and accident cases was about 30,000, or a ratio of 1 to 8 of the townspeople. Although the great majority of the patients came from the working-classes, yet the total of the workmen's contributions, apart from the Saturday and Sunday Funds, was only £383, and the proceeds of the Saturday and Sunday Funds were steadily declining. The collections last year in Manchester and Salford together amounted to a little over £7000. Newcastle-on-Tyne collected three times as much. It was reported that the King had graciously accepted the position of Patron. In connexion with the resignation of Mr. Boutflower, it was stated that the services given to the hospital by Mr. Boutflower and his father had extended over 94 years.

Manchester Crematorium.

The annual meeting of the supporters of this institution was held on Oct. 27th. The report showed a profit of £172, and the chairman stated that the sentiment in favour of cremation was growing, as shown by inquiries from various bodies and societies to inspect the institution. The Bishop of Carlisle is now associated with the Bishops of Manchester and Oxford in approving of this method of disposition of the bodies of the dead. One speaker advocated the view that there ought to be compulsory powers to cremate all bodies of persons who had died from infectious diseases.

Ancoats Hospital: Its Work and Deficit.

At the annual meeting of the friends of Ancoats Hospital it was stated that 23,890 cases of accident had been treated in the hospital, as against 23,279 in the previous year. The in-patients numbered 1450, out-patients 10,547, and patients treated in their homes 1710. The hospital authorities hope that with the Royal Infirmary in its new site, they may expect some relief in the accident department. The increase of new casualty cases at the rate of 65 per day as compared with 41 in 1908, is seriously taxing the resources of the hospital. The system of "recommends" has been given up, and all sick poor in this busy industrial district who come to the hospital are duly treated. The income is £6879, and the expenditure £8660, leaving a balance on the deficit side on the year's account of £1780. This, with the deficits of previous years, makes a total debt of £9321 due to the bank. A special appeal was made on behalf of the hospital some time ago, whereby £8667 were received in donations, and £727 in new annual subscriptions. In the report it is stated that as regards the Insurance Bill "it is difficult at present to see any provision in it which would tend to the relief of the in-patient department, the costly part of the hospital's work."

The Insurance Bill: Uncompromising Resolution.

A meeting attended by over 350 members of the profession in Manchester and Salford was held in Manchester on Nov. 3rd to hear an address by Mr. J. Smith Whitaker, the medical secretary of the British Medical Association, on the Insurance Bill and the position of the profession under its provisions. Dr. Helme presided. The following resolution was carried unanimously:—

That this meeting affirms its unwavering adherence to the declared policy of the British Medical Association (including the six cardinal points) in relation to the National Insurance Bill, and declines to accept any amendment that would defeat the object of that policy, and is resolved to refuse any arrangements for medical attendance and terms which do not comply with that policy and afford adequate remuneration.

Midwives and the Insurance Bill: Their Complaint and Demand.

A meeting of midwives was held in Manchester on Nov. 2nd to urge that working midwives should be appointed on all local committees for the administration of the maternity benefit under the Insurance Bill. The general contention of the speakers was that notwithstanding there are 30,000 women on the Midwives Register, no provision is made for their particular employment under the Bill. Further, that the representation of medical men

on all committees under the scheme, coupled with the exclusion of the midwives, would lead to women losing much of their work. One speaker stated that they had been unable to secure an interview with Mr. Lloyd George. Under the Bill the midwife had no security at all for the engagement of her services and the payment for them. Another speaker said that 30,000 men belonging to a profession affected by the Bill would not have received the treatment which the voteless midwives had received. A resolution was carried calling on the Government to provide for the appointment of working midwives to the local committees dealing with the administration of maternity benefits under the Bill.

Nov. 6th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

Winsley Sanatorium.

THE board of management of the Winsley Sanatorium has given its assent to a scheme of extension which has long been under careful consideration. The plan which has been adopted provides better accommodation for the resident medical officer, matron, and servants, with some increase in the dining-hall, kitchen premises, and storerooms. This will set free for patients rooms at present occupied by the staff. The medical officer is to have a self-contained house forming part of a new administrative block, and the whole extension, which will make the accommodation sufficient for 100 patients, is to be carried out on the block system. It is expected that this will cost about £9000, with very little addition to the cost of upkeep. The balance in hand amounts to over £4000; the remainder will, it is hoped, be made good by further subscriptions (some of which are already promised), by the accumulation of the surplus on revenue during 1912 and 1913, and by selling or letting the added beds (30 in number) to local authorities. The Bristol members of the board felt compelled to make their acceptance of the scheme subject to "the distribution of the beds being made on the basis that the present holders of beds have the additional beds allocated in the proportion of their present holding." This is because it is thought that under the provisions of the National Insurance Bill, if and when it becomes law, Bristol may have to reconsider the whole matter and set up for herself a comprehensive scheme for the treatment of tuberculosis, including a separate sanatorium.

Bristol Medical School Dinner.

The annual dinner of the Bristol Medical School will be held on Tuesday, Nov. 21st, at the Royal Hotel, College Green. The chair will be taken by Mr. C. E. S. Flemming, of Bradford-on-Avon, and the guest of the evening will be Professor Howard Marsh, Regius professor of surgery in the University of Cambridge and Master of Downing College.

Bristol School for Mothers.

The Bristol School for Mothers has had a most encouraging career so far, and there was a good attendance at the annual meeting on Nov. 6th. When the school was opened two years ago there were ten members; now there are 100 attending more or less regularly, and the average number present at each weekly meeting is 35. The chief speaker was Dr. Florence Willey, who spoke of the paramount need for caring for working-class mothers during pregnancy and lactation, and securing adequate rest and food for them. Dr. Annie Cornall, who is medical officer to the school, said that it was difficult to attract the poorest and most ignorant mothers to their meeting, and hoped that the Notification of Births Act, about to be adopted in Bristol, might help in this respect. Dr. D. S. Davies, medical officer of health of the city, spoke of the valuable help given by the school to the city health committee during the summer outbreak of diarrhœa in lending two lady health visitors to the city for the time being. The work of the school is about to be municipalised, in so far that a lady medical officer is to be appointed, with two lady health visitors to assist her, but, as Alderman E. H. Cook observed, it is to be hoped that the voluntary organisation will continue its work in conjunction with these new officials. The accounts show a small deficit, but this will no doubt be made good.

Memorial Hospital to the late Sir Charles Dilke.

A meeting of Radical Members of Parliament was recently held in the House of Commons, when the proposal, referred to in THE LANCET of Sept. 9th, to erect a hospital in the Forest of Dean, Gloucestershire, as a memorial to the late Sir Charles Dilke was approved. It is proposed to issue to every Member of Parliament a circular, signed by representatives of all parties, inviting support for the scheme. Earl Beauchamp is chairman of the memorial committee, Sir W. Wedderburn, vice-chairman, and Mr. H. Webb, M.P., treasurer.

The Sewerage of Bath.

A Local Government Board inquiry was held recently at Bath into an application of the local town council for permission to borrow £35,000 for purposes of sewerage for the parishes of Twerton and Weston. This is part of the larger scheme of sewage disposal for Bath which is now being carried out, as these two parishes were included within the city boundaries on Nov. 1st.

The Bridgwater Hospital.

A meeting was held at Bridgwater on Oct. 28th, under the presidency of the mayor, to consider the financial position of the Bridgwater Hospital and the question of providing additional accommodation for women and children. After some discussion it was resolved to hold a carnival in 1912, the proceeds of which are to be devoted to paying off the debt on the hospital. It was stated that the centenary of the institution will take place in 1913, and in connexion with the celebration of this, and as a memorial to the late King, it was decided to add a new children's wing to the hospital. A general committee was appointed to carry out these objects, and several subscriptions were promised towards the erection of the new wing, including £100 from Mr. S. Sanders, M.P., £56 from Mr. G. Porter, and several smaller sums.

The Injunction of a Manufacturing Nuisance.

In the Chancery Division, before Mr. Justice Parker, a case which has caused much interest in the "Three Towns" was concluded on Nov. 2nd. It was an action brought by the mayor and burgesses of Plymouth against the Plymouth Fish Guano and Oil Company. The plaintiffs asked for a perpetual injunction to restrain the defendant company from carrying on at their factory and works the manufacture of fish guano, fish manure, oil, or other products of putrid and decomposed fish offal and refuse so as to cause a nuisance. The defendants denied that "they used offensive matter, and contended that their business was a lawful one and not dangerous to public health." The judge eventually gave judgment for the plaintiff corporation and granted the injunction.

Medical Candidates at the Municipal Elections.

At the Barnstaple (Devon) municipal election three medical men were amongst the 13 candidates for the six vacant seats, and two of these, Dr. Alexander John Kendrew and Dr. George Stephen Ware, were eventually elected. The election created great interest in Barnstaple, and the local press stated that the Insurance Bill was the cause of the medical men becoming candidates. Notwithstanding a denial of this assertion, the *Western Morning News* stated that it was rumoured that members of the Friendly Societies would not support the medical men. At the Bath municipal elections two medical men, Dr. Preston King and Mr. Richard James Herbert Scott, were elected.

Death of Dr. Thomas Henry Stocker Pullin.

Dr. T. H. S. Pullin died at his residence, Abernethy House, Sidmouth, on Oct. 26th, in his eighty-eighth year. Dr. Pullin received his medical education at St. Bartholomew's Hospital, and qualified as M.R.C.S. and L.S.A. in 1850. Twelve years later he graduated as M.D. at the University of St. Andrews, and in 1882 he obtained the F.R.C.S. of Edinburgh. Shortly after qualifying Dr. Pullin acted as medical officer of the board of health during the cholera epidemic at Portsmouth, and for a short time was assistant surgeon at Christ's Hospital, London. He then came to Sidmouth, where he soon established an extensive practice. He was surgeon to the Sidmouth Dispensary, medical officer of health of the urban district, Admiralty surgeon, and certifying factory surgeon. Dr. Pullin was very popular in Sidmouth and East Devon. He took a great interest in everything relating to the welfare of Sidmouth. The funeral took place on Oct. 31st and was largely attended.

Nov. 7th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Medical Societies.

THE Edinburgh Medico-Chirurgical Society opened its ninety-first session on Nov. 1st. Dr. Byrom Bramwell delivered his valedictory address, and on the motion of Sir James Affleck was cordially thanked for his conduct in the chair. Mr. J. M. Cotterill was elected to the chair, Mr. Alexander Miles became senior secretary on the resignation of Dr. F. D. Boyd, and Dr. J. Stewart Fowler was elected junior secretary. It was intimated that a discussion had been arranged on the treatment of fractures, to be introduced by Mr. C. W. Cathcart, and one on vaccine-therapy by Dr. James Ritchie, of the Royal College of Physicians' Laboratory.—The Edinburgh Royal Medical Society has appointed the following Presidents for the coming session: Dr. R. G. Gordon, Dr. T. C. Ritchie, Dr. F. R. Luke, and Dr. J. T. Morrison. Dr. Gordon is senior president. This is an excellent as well as an ancient society and can be warmly commended to the students. It is perhaps the best field for his training as a thinker and speaker on medical topics.

The Edinburgh New Nursing Home.

The promoters of the scheme to provide a nursing home at a moderate cost for persons of limited means, to which reference was made in THE LANCET of Sept. 9th, are to be congratulated on having obtained from the public the money for which they appealed. They have secured suitable property for the purposes of the scheme in Chalmers-street.

The General Medical Council.

Dr. Norman Walker addressed his constituents in Edinburgh on Tuesday evening, Oct. 31st. Dr. G. A. Gibson occupied the chair. There is no other candidate.

Opticians and the Glasgow Eye Infirmary.

At a recent meeting of the council of the Institute of Ophthalmic Opticians, held in London, reference took place to the application recently made on behalf of the Glasgow Eye Infirmary to the Board of Trade for registration under the Limited Liability Act, without the necessity of the word "limited" being added to the name of the institution. It was reported that the powers sought would be detrimental to the interests of opticians, and that the Law and Parliamentary Committee of the Institute had decided to oppose the granting of the licence. As a result of the negotiations with the Board of Trade the clause under which the Glasgow Eye Infirmary would have been empowered to supply spectacles to its patients was deleted from the licence ultimately granted.

Dental Treatment for Glasgow School Children.

At a meeting of the Glasgow School Board the minutes of the committee on the medical inspection of scholars showed that a motion had been adopted "that dental treatment be given to a child undoubtedly necessitous, and that steps be taken to have the competency of paying for that treatment tested forthwith by a special case in the Court of Session." This question came up four months ago, when the medical officer of the school board reported that over 90 per cent. of the school children in Glasgow had bad teeth and 50 per cent. had very bad teeth. The suggestion was made by the committee that the board should give advice to parents as to what they should do with their children to prevent the state of matters growing worse. The difficulty was that they did not know exactly whether or not they had the legal power to do such work. It was thought that until they got the opinion of the court it would not be proper to embark on such expenditure. Already they were paying £4000 a year for medical inspection. If they were deliberately to begin dental treatment it would cost £500 in the first year and might entail medical treatment which would end, perhaps, in the cost running to £5000. Testing the case would cost about £300. An amendment was proposed to the minutes, suggesting that the board, instead of testing the case, should go ahead with the dental treatment of children. A sum of £500 was a great deal to give lawyers for advice on a matter which was perfectly clear from the department's memorandum. In Deptford they had treated over 3000 children for £446, with successful results in from 70 to 80 per cent. That was the price of the Court of Session action proposed. After a long discussion the minutes were carried by a large majority.

Medical Appointments at Glasgow.

Dr. Carl H. Browning, formerly lecturer in bacteriology, has been appointed University Lecturer in Clinical Pathology and Director of the Clinical Research Laboratory at the Western Infirmary, Glasgow.—At a meeting of the governors of Anderson's College Medical School, Glasgow, held last week, Dr. William Dove Macfarlane, jun., surgeon to the Royal Samaritan Hospital for Women, was appointed to the chair of midwifery and gynæcology at the school.

Wick Parish Council and the Local Government Board.

At a recent meeting of the Wick parish council a letter was submitted from the Local Government Board in regard to the proposed reduction of the salary of Mr. G Banks, medical officer of the Northern division of Wick parish. After careful consideration the Board was unable to agree with the council that there was reasonable ground for reducing the salary of the medical officer. It was reckoned that there were 350 poor on the roll in the parish, and that half of the total was in the Northern district. The medical officer had to attend 175 persons. Having regard to these figures and to the extent of the parish, the Board could not regard as excessive the salary of £56 at present allowed to Mr. Banks. It was also pointed out that Mr. Banks's period of service had extended over 40 years.

Dundee Parish Council and Vaccination.

The Local Government Board has communicated with Dundee parish council as to its inaction in regard to vaccination defaulters. At the last meeting of the Dundee parish council a motion to defer proceedings against defaulters for three months was carried. On the clerk's reporting proceedings to the Local Government Board, the Board sent a communication to the effect that the parish council had a statutory duty to perform in respect of the list of defaulters, and that if it failed to perform it the Local Government Board was empowered to compel it to do so. The Board looked to the parish council reconsidering its decision, and thus relieving the Board from taking steps. Notice of motion to rescind the previous decision has been given by one of the members of the parish council.

Nov. 6th

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ireland and the Insurance Bill.

ON Nov. 2nd a deputation of Irish medical men met the Chancellor of the Exchequer by appointment in reference to the Insurance Bill. After some of them had spoken, Mr. Lloyd George, in a most fair way, said he was willing that "medical benefits" should extend to Ireland as they did to England and Scotland, but that the Nationalist Members thought otherwise, and so he would yield to them; but he suggested that the deputation should see the Irish Members. An informal meeting subsequently took place in the House of Commons, at which it came out that the Nationalist Members had drawn up a series of amendments relating to the Bill as it affected Ireland, and that "medical benefits" had been left out. They threw the blame for this on the Irish medical profession, for a letter had been sent to the secretary of the combined British Medical and Irish Medical Associations' Committee to meet the subcommittee of the Nationalist Members dealing with the Insurance Bill on a certain day in Dublin, to discuss the matter, and on that day no medical man appeared. They naturally concluded that the medical profession did not want "medical benefits." In explanation it was pointed out that the secretary of the combined medical committee was in the south of Ireland, and that when the letter reached him the date of the meeting was passed. The deputation, having made this explanation so as to clear up a very natural misunderstanding, pointed out that they did not object to the Bill if it applied to Ireland in the same way as it did to Scotland and England; what they protested against was the plan suggested originally by the committee of the Nationalist Members, which they regarded as unworkable. The Nationalist Members pleaded

financial grounds. However, they asked the deputation to meet them again and to table their views. Next day, Nov. 3rd, the suggested meeting took place, and the deputation put forward as their plan the six points adopted by the British Medical Association, to which the Irish Nationalist Members would not agree. It is clear that the Irish Nationalist party is divided on the matter, the majority being rural representatives, and, pressed by their constituents, say the amount to be paid by farmers and their workers is too high and that they are already looked after medically by the dispensary medical officers, while the minority—representing the towns—see that they will have difficulty with their labour constituents. Further, some of the Irish Nationalist Members favour the appointment of medical inspectors to go about examining for certificates, &c. Others say: "Give the dispensary doctors a small (2*s.* or 3*s.*) grant for certificates, drop 'medical benefits,' but accept the sickness and sanatoria part of the scheme." The medical profession would rather let the Bill drop—so far as Ireland is concerned—unless it is applied in the same way as in England and Scotland; but the Nationalist Members are feeling the difficulty they will have with the Labour Party, especially in the industrial centres, if they abandon the "medical benefits." Is a skilled workman who in England will have "medical benefits" to lose these benefits when he comes over to Ireland? The Nationalist Members have been looking everywhere for some plan to suit Ireland, but so far no constructive legislative scheme adapted to both urban and rural districts has been evolved. It may appear yet in their amendments.

Medical Inspection of Schools in Ireland.

The Meath Hospital is the only Dublin hospital which has this year kept up the old custom of opening its session with an address from one of the staff. Dr. Oliver St. John Gogarty, surgeon to the hospital, chose as his subject the need for medical inspection of schools in Ireland. He pointed out that according to the reports of the medical officer of the Education Committee of the London County Council one child in every three required medical attention. Defects of the nose and throat were the most common. Dr. Gogarty traced the evil effects, mental and physical, of adenoids. He protested against the long school hours in force in Ireland, and held that if the children were in good health shorter hours would be sufficient to give the same amount of instruction. Medical inspection of schools would pay its own way in the increased efficiency of the schools and the increased health of the children. Dr. Gogarty added that the Treasury gave for all forms of education in Ireland £1,632,000, whereas for Scotland the grant was £3,250,000. The address has attracted much attention in the public press.

Health of Belfast.

The report of the medical officer of health for the period from Sept. 17th to Oct. 14th showed that the general death-rate was 17·6, the zymotic rate was 4·0, and that from chest affections 3·2. Of the 170 cases of infectious diseases notified during this period, 99, or 58·23 per cent., were scarlet fever, 18 were typhoid fever, and 26 were diphtheria. The excessive mortality from zymotic disease, as compared with 1910, is almost entirely due to the number of deaths registered as due to epidemic diarrhœa and enteritis, 105, or 89 74 per cent., of the deaths registered from zymotic diseases being attributed to this cause. This report brings us up to the middle of October, but it appears that during the month of October 140 cases of scarlet fever, 25 of diphtheria, and 22 of typhoid fever were notified, while the death-rate from zymotic disease during that period is said to be about 4·5.

Belfast Water-Supply.

Fortunately, the wet weather of the past fortnight has improved the water-supply of Belfast. The month of October was the wettest month since December, 1910, although only on 12 days did rain fall. The rainfall in Belfast was 3·57 inches, and Sunday, Oct. 29th (on which 0·94 inch fell), was the wettest day this year in that city. In some places in Ulster the rainfall in October was even heavier than in Belfast; for instance, at Seaforde, Co. Down, on 13 days 4·41 inches fell, while in the Mourne Mountains the rainfall was over 6 inches, and 1·87 inches fell on Oct. 30th. On one occasion within 24 hours a little over 2 inches was recorded, so that the flow in the Kilkeel and Annalong rivers increased from 6,000,000 to 600,000,000 gallons; but owing to the utter want of management in not having a reservoir in the Mourne district for storage a large amount of this abundant supply ran to waste. Even with this copious rain (and it is still continuing) the supply is only about one-fourth of what is usually available at this time of year, hence the city is still given a restricted quantity of water. It is said that the Water Commissioners are trying to find a site for the storage reservoir in the Mourne district. It seems strange to the ordinary observer that this was not settled before the conduit pipes passing through Slieve Donard mountain were constructed at enormous cost, which simply bring to Belfast a portion of the water of the Annalong and Kilkeel rivers. Had a reservoir been made there long ago, Belfast, like Glasgow and London, would have no need to give a restricted supply at present, and citizens would not have been expected to pay for what they do not get.

Scarlet Fever in Banbridge and in Londonderry.

A serious epidemic of scarlet fever is prevailing in Banbridge, where at present there are about 56 patients under treatment in the hospital. Fortunately the disease is of a mild type, and so far the mortality has been *nil*. The national schools are to be closed some time longer as a means of checking the disease. On the other hand, the type of the disease in Belfast is severe. There is also at present an epidemic of scarlet fever in the waterside district of Londonderry, a large number of children being ill with it in the workhouse fever hospital.

Typhoid Fever in Tyrone and Fermanagh Asylum.

A serious outbreak of typhoid fever has occurred amongst the attendants, nurses, and patients in Tyrone and Fermanagh Asylum at Cranny, Omagh. Up to Nov. 4th, 70 persons in all, about 20 being attendants and nurses, have fallen victims to the disease. Three deaths have already taken place. More male than female patients are ill. At a meeting of Omagh rural council held on Nov. 4th Mr. J. J. Todd, medical officer of health, reporting on this outbreak, said he was of opinion that the asylum authorities should be requested to erect a septic tank, the sewage being at present discharged into the river, which immediately passed through the town of Omagh. He urged that the rural council should direct that the insanitary disposal of the sewage from the institution should cease. But nothing was done.

Nov. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Prophylaxis and Treatment of Syphilis and Yaws in Martinique.

SINCE the discovery of "606" its employment and results have given rise on all sides, both in France and abroad, to lively discussion in scientific societies. Some there are who recognise in it a universal efficacy in all cases of syphilis, and even go so far as to attribute to it radical cures. Others charge it with inducing serious inconveniences, and, when it is used injudiciously and without all necessary precautions, even death itself. Finally, some accord to it its proper place, that of a very powerful drug, which has given excellent results in the hands of those who know how to select appropriate cases and to use precautions. A communication by MM. Noc and Stévenel to the Society of Tropical Pathology has revealed the gravity of syphilis in Martinique, and has confirmed in this respect the prior demonstrations of Kermorgant. These observers have found in "606" an admirable remedy, especially in regard to the prophylaxis of syphilis in hot climates. Their results have been most satisfactory in 44 syphilitics, as well as in two subjects of yaws submitted to treatment with it. The convenience of this treatment by one or two intravenous injections has caused the negroes, who hitherto have shown themselves rebellious against mercurial treatment, to come in crowds to be injected with "606."

A Clinique of Blind Masseurs in Paris.

A body of blind masseurs have recently opened in Paris a clinique for treatment by massage. In consequence of the extreme delicacy of their sense of touch the blind succeed in an exceptional manner in this occupation. They are also the

most discreet of masseurs. Many mineral-water resorts, such as Vichy, Uriage, Plombières, Néris, Châtel-Guyon, Bourbonne, and Bourbon l'Archambault, possess experienced blind masseurs, both male and female. In Japan, moreover, massage is in point of fact a monopoly for the blind, so well known that the same word designates both masseur and blind. As these experiments at French watering places have proved favourable for them, under a subvention from the Minister of the Interior, a special course of massage for the blind has been instituted under the conduct of a blind medical man, Dr. Fabre. Success must surely be wished for this institution, which opens an honourable means of livelihood for the blind—a class for whom professional openings have hitherto been limited.

The Struggle against Absinthe.

For a long time means have been sought in France of making war on absinthe, at least to limit its consumption as much as possible. A new Bill has recently been presented to interdict the manufacture and sale of absinthe. This Bill is very sweeping: it ordains that the manufacture, importation, circulation, and sale of every liquor of the nature of absinthe shall be interdicted. It prescribes a penalty of from three months' imprisonment to two years' imprisonment, with a fine of from 500 to 10,000 francs, or of either of these penalties. Importers and vendors are to be punished with imprisonment of from three months to a year, or a fine of from 100 to 5000 francs, or both. The tribunal may also altogether prohibit from trading in drinks anyone who shall be reconvicted, and the interdicted drinks and material shall be confiscated. The Bill (if it passes) is to come into force from the date of its passage as regards the manufacture, and within two years as regards the circulation and sale.

The Sale of Serums.

In THE LANCET of Sept. 9th I referred to a decree of the Court of Cassation, forbidding to the medical profession the sale of serums, even when prepared and injected by themselves, without the authority of the Academy of Medicine. On Oct. 27th this question was definitely settled by the Correctional Tribunal of the Seine. Henceforth, therefore, unless the Court of Cassation should reopen the question, medical men will not be able to augment their fees with the cost of a serum that has not received the sanction of the Academy of Medicine. This novel legislation prohibits a practice that has become general, and, as a result, there is a considerable outcry in the medical world. The case before the Tribunal was that of an appeal made by Dr. Régnier against a judgment by default, which had condemned him to pay 1000 francs as damages towards the Syndicate of Pharmacists of the Seine for a breach of the law regarding the sale of serums. Dr. Régnier was in the habit of injecting his syphilitic patients in a clinique named after him with an antisyphilitic serum obtained from immunised apes. But he also sent this serum into the provinces or to patients on the request of their medical advisers. The serum was injected only by the medical men. Dr. Régnier represented to the Tribunal that the price asked by him included not only the cost of the serum, but also his fee for personal services, microscopical examinations of the blood of the patients, and the direction and surveillance of the treatment. The Tribunal reduced the fine from 1000 to 100 francs.

Ovarian Grafting.

When a woman on account of ovarian trouble of any kind is obliged to undergo removal of the ovaries, various disturbances of health arise, troubles that are greater in proportion as the patient has yet before her many years of functional life. To ameliorate this condition, Dr. Tuffier, since 1906, has performed 130 ovarian graftings, which he considers permissible in case of complete removal of the ovaries. In five cases the grafts were taken from another woman, in 109 cases from the patient's own ovaries, and in 87 cases he has grafted a single ovary. The "hetero-grafts" demand special conditions, which can rarely be obtained. In only three cases out of 119 cases followed up has the grafted ovary been eliminated. In 116 cases it has been well tolerated, and then either it has been absorbed or remained *in situ*, though inert, or else after a time of torpor lasting from one to five months, it has become the seat of monthly congestions which may continue for two years. When the woman has no uterus the grafts give no relief from the troubles due to suppression of the ovaries. But when the uterus has been preserved and the graft takes, menstruation becomes re-established, preceded by congestive phenomena in the region of the graft from one to five days before menstruation. This is not due to the presence of a supernumerary ovary, for when such exists, as Dr. Tuffier has observed in a strikingly decisive case, the graft does not become the seat of congestive phenomena; in such a case the troubles disappear as long as menstruation lasts. These troubles, therefore, are to be attributed to the suppression of menstruation, which is a means of eliminating toxins.

Nov. 7th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Failure of an Action for Libel brought by one Medical Man against Another.

IN an action for libel recently heard in the Vienna High Court a certain Dr. Panesch, M.D. Vienna, claimed damages from Dr. Grün for having been made the object of calumnious remarks by the latter. Dr. Grün had, in the periodical press and in medical clubs, remarked that the plaintiff, although he pretended to treat patients "by more natural methods" than the orthodox practitioners, in reality employed the ordinary prescriptions and remedies which are in everyday use. Dr. Grün also stated that Dr. Panesch was in public a vigorous antivaccinator, whilst in private he performed vaccinations just as any regular practitioner would. It must be explained that there exists in this city a certain political party whose main object is to excite opposition to medical science and to hinder medical progress and research. This party is also responsible for arousing animosity against foreigners who have been appointed professors in Austrian universities, and has even succeeded in scaring some of them away. Dr. Panesch was for some time the editor of the journal which expresses the views of this party, and even now he is one of the staff of *Natürliche Heilmethoden*, which is a decided opponent of regular medicine. In the hearing of the case the defendant was able to prove that the plaintiff had vaccinated and prescribed within the last few years regularly in accordance with recognised orthodox methods, but that he, nevertheless, informed his patients that his way of treatment differed entirely from that of other doctors of medicine by applying only "natural remedies," and that he always used to pose as an adherent of and believer in a new system of pathology. The judge expressed in a most severe manner his disapproval of the plaintiff's action, and inflicted a fine upon him for abusing the patience of the court.

The Vienna Medical Council.

The election of the new Medical Council (Aerzte-Kammer) for Vienna took place not long ago, and with very few exceptions the former members were returned. Professor Finger will again be chosen President of the Council, whilst Dr. Gruss will be Vice-President. The main object of the recent election was the same as last time—namely, to unite all sections of the profession by nominating and electing all the leaders of the different parties as they may be called, and thus to ensure a uniform working for the benefit of the profession. The Vienna Medical Council has naturally more influence than any other, representing as it does the capital of the Empire and the University, and some very important work will soon be brought before it, for the new Medical Act with its numerous regulations will have to be considered, and the profession is far from being satisfied with its provisions and wording as it stands at present.

Adulteration of Food Products.

The recent universal rise of prices for all articles of food and other absolutely necessary commodities has led dealers to attempt to increase their profits by adulteration. On the other hand, the public naturally try to get full value for their money, and the market inspectors all over the country have consequently been instructed to be on the alert, especially as regards milk, butter, and flour. The result is that numerous prosecutions for adulteration of the above-mentioned articles are now proceeding, and it must be acknowledged that the Home Office does its utmost to protect the public. In order

to facilitate the supervision of the milk-supply surprise visits are made at the smaller shops, and instruments for testing milk are issued to dairymen. The scarcity of milch cows has caused a large importation of Dutch and Russian butter into Austria; this branch of the provision trade is strictly controlled by the State, whilst the importation of meat is forbidden—a decidedly unpopular regulation. The fact of the matter is that the recent epidemic of foot-and-mouth disease in Austria, which proved fatal to 30 per cent. of the cattle, has created such a scarcity of meat, that the importation of frozen meat will have to be permitted sooner or later without reference to political considerations.

The Advantages of the Winter Term for Post-graduate Study by English Visitors.

The winter session of 1911–12 will be a memorable one for the medical faculty of the university, as a large part of the new hospital will be in use and the new clinics are justly an object of pride for every Austrian medical man. The only drawback involved in the division of clinical teaching between the old and the new hospitals is the loss of time for the students. Amongst the lectures, the majority of which are open to any students and medical men from any part of the world, there are special courses conducted in English; these latter are intended chiefly for the benefit of the numerous English and American visitors at present completing their studies in this city. The Americans have created a colony here, having their medical club, their café, and their lecture arrangements. Through their influence it has come about that an English-speaking medical visitor may obtain the advantage of German scientific instruction and practice, may see a number of operations, and may perform some himself, without speaking a single word of German, all the conversation and oral instruction being conducted in his native tongue. The fees for these classes are comparatively low—from £2 10*s.* to £4 4*s.* per month, and there is a wide range of subjects, in any one of which a class may be formed if a few applications to that effect are made.

Nov. 6th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The Epidemic of Cholera.

THANKS to the vigorous measures of the sanitary authorities and also to cool weather the cholera epidemic has been markedly on the decrease in Constantinople. Last week not a single death was recorded. To-day, however, the Turkish newspaper *Yeni Gazetta* reports that cholera has visited the large asylum for the insane at Scutari. According to this daily paper six inmates were stricken last Monday. The symptoms and the bacteriological examination showed that the cases were genuine cholera Asiatica. It is asserted that the water sources at Scutari are contaminated. The sanitary commission is investigating the matter. During the full swing of the epidemic I offered myself to the municipal authorities, and was attached to the sanitary station of Peri-Pasha, on the Golden Horn, where cholera raged most. I thus gained experience, not only in the course of the disease and its treatment, but also in the superstitious attitude of the people of that particular district, for the most part destitute and ignorant, to the epidemic and to the medical profession. I found that lactic acid and opium were efficient means of combating the first symptoms. I also found thymol and, in later stages, hypodermic injections of morphine of considerable use. The most difficult part was to persuade the people of the urgent necessity of immediately reporting to the medical man every suspicious case. Frequently the patients were utterly neglected by their relatives, who preferred every possible domestic remedy to any medical intervention. Some actually believed that it was in the interest of the physician to poison the cholera-stricken patient in order so much the quicker to stamp out the epidemic. On more than one occasion I found a dead body thrown out into the street during night time. It was impossible to trace whence it came, so secret was the matter kept by the inhabitants. In some quarters of Stamboul the people conspired against the medical authorities and the attendant physicians and caused them worry and even personal injury. The people dreaded most of all hypodermic injections and would often oppose them fiercely. Keeping a contaminated house under strict cordon was another difficulty. No matter how sharp was the watch kept, the inmates would always succeed in escaping supervision. They would escape from windows, thus helping the propagation of the disease, frequently knocking down the sentinel and running away. On one occasion, however, a Jew tried to escape and was shot dead by the sentinel. This put a stop to further attempts at evasion.

Turkish Cholera Remedies.

Among the orthodox Turks the old and the priests were always ready to give counsels as to how to live and behave during a cholera epidemic. Frequently they offered advice in treatment, asserting at the same time that doctors were the real cause of the trouble, and should be shunned just as much as the epidemic. Here are some remedies against cholera recommended by some old-fashioned Ottomans: (1) Drink infusion of juniper berries; (2) carry with you an agate stone or on your neck a stone of hyacinth; (3) never fail to have in your pocket a bone of a dead child; (4) masticate pimpernel; and (5) since cholera is mostly caused by the moon, drink decoctions of laurel fruit when the planet Mars or Mercury is in the ascendant, as these planets are the enemies of the moon.

Cholera in the Provinces.

In the provinces the epidemic has also diminished, but in a lesser degree. There the spread of cholera was due to the extremely bad conditions of living, to the dirt of the streets, to the want of proper canalisation and lack of drinkable water, and to the ignorance and obstinate refusal of the lower classes of the population to follow medical advice. The great scarcity of provincial medical men was another very serious cause. Often the old women of a place attempted playing the rôle of doctors, with disastrous results. Thus it was reported from a village that a number of such old Megæras had shut a young cholera-stricken woman in a hot oven, and the unfortunate patient died from suffocation. I should mention the utter inadequacy of medical salaries as paid by the municipal authorities, of which physicians have frequently complained to me. I suppose this unsatisfactory state of affairs is largely due to the present Italo-Turkish war, with which the whole attention of the metropolis is taken up. The only topic of conversation is war, which drowns all other interests.

Nov. 2nd.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS)

Continued Prevalence of Rabies.

OWING to the long-enforced laws in Great Britain compelling the muzzling of dogs, rabies is practically unknown in England. The same is the case in Germany and Denmark. The zoophilists of the United States are fond of stating that there is no such thing as rabies, and that the well-known symptoms are merely psychical and produced by fright. The current monthly *Bulletin* of the Department of Health of the City of New York, however, while admitting that rabies is among the rarest of fatal diseases, shows that during the first eight months of 1911 the department investigated 2462 cases reported of dog-bite, among which 7 genuine cases of rabies developed. Many of the two thousand and odd cases were submitted to the Pasteur treatment, which is itself as tedious and painful as a disease, and compels the sufferers to undergo great expense, discomfort, and loss of time. The number treated at the Pasteur Institute alone during the eight months was 312, as compared with 262 for 1910 and 182 for 1909. The victim is obliged to shoulder the expense, which, the *Bulletin* says, is unfair. The power of the health department should be extended; at present it is limited to investigation of the reported attacks by dogs, the destruction of undoubtedly rabid dogs, the administration of Pasteur treatment to willing patients, and to an emergency power to kill unmuzzled animals in times of danger. This last privilege is so objectionable to dog lovers that its practice is impossible. There is a State law enabling the Commissioner of Agriculture to quarantine the dogs of an infected district, but this is inadequate. Education of dog owners is demanded

and liberty to keep down the stray dog population. It has been suggested that municipal and sanitary authorities throughout the country should devise some method to protect the public by the introduction and enforcement of measures similar to those that have proved successful in England, Germany, and Denmark The licensing of dogs in New York, alone among great cities, is left to a private corporation, the Society for the Prevention of Cruelty to Animals.

Conference of Sanitary Officers of New York State.

The second annual meeting of the association of these officers began in New York on Oct. 24th. In the State there are 1400 sanitary districts, nearly all of which were represented. The State Legislature was roundly denounced for decreasing the appropriation for the aid in prevention of tuberculosis, while raising that for the study of diseases of the lower animals, hog cholera in particular, and the attention of that body was called to the necessity for more stringent regulations on the practice of spitting in the streets. On the evening of Oct. 26th, Dr. Simon Flexner, director of the Rockefeller Institute for Experimental Research, stated that the institute had discovered a serum for the cure of spinal meningitis, which was to be injected directly into the cord. An address was given by Dr. C. E. Walton on "The Doctor and the Health Officer as Co-labourers." Dr. Walton thought that promiscuous kissing, especially among children, demanded legislative interference. Dr. William H. Guilfoy, registrar of the New York health department, said that New York had at last succeeded in obtaining a satisfactory system of registration of births and deaths, the only trustworthy one in the whole country. The facts that children could not enter the public schools without having certificates that they were six years old, or get work in a shop or store without producing working permits, had been strong aids to efficient registration. An International Waterway Commission to prevent the contamination by sewage of the rivers and lakes on the boundaries of Canada and the States was advocated by Dr. McCullough, chief of the health department of Ontario, Canada. Laws to regulate cold storage of food were proposed by many speakers. Mr. R L. Cox, counsel for the Association of Life Insurance Presidents, complained of the inadequate equipment of many health departments in the States, and urged the establishment of a clearing-house of health departments. On Oct. 27th the members were invited to inspect the Rockefeller Institute. Dr. W. S Magill, director of the State Hygienic Laboratory, informed the members that although the directions on each package of diphtheria antitoxin sent out by the State were plain enough, he found that not more than one physician in a hundred followed them implicitly.

Infantile Paralysis a Dust Disease.

At a meeting of the Neurological Section of the New York Academy of Medicine on Oct. 10th Dr. Marcus Neustaedter gave an account of experiments conducted by him and Dr. W. C Thro, of the Medical Department of Cornell University, with regard to the causation of acute poliomyelitis. Dr. Neustaedter holds that dust plays a prominent part in the spread of the malady. He drew the following conclusions: first, that the disease is essentially an infantile one, prevailing principally among very young children who play upon the floor; second, that it occurs mostly in the dry season; third, that the character of the neighbourhood and conditions of life do not play a material part in its spread; fourth, that children in the same family may be attacked one after the other, and that in a given house children may be attacked in different families in quick succession and on the lines of neighbourly communication; and fifth, that the upper air passages seem to be the channels of infection. Experiments on monkeys appeared to show fairly conclusively the important part played by dust in spreading the disease.

Dental and Eye Clinics for School Children.

The Board of Estimate of New York City has under consideration a plan to provide, at the cost of the city, oculists and dentists to treat ocular and dental defects in children in the public schools. The board's special committee on health, hospitals, and charities has recommended that these duties devolve on the Board of Health's division of child hygiene. The committee's report recommends that provision be made in the budget of 1912 for municipal dental clinics.

The Milk Stations of the New York Milk Committee to be Closed.

The 31 stations of the New York Milk Committee are to be closed on Nov. 1st, in accordance with the plan of campaign announced at the beginning of last summer. The committee, however, has suggested that the city assume supervision of the infants enrolled at these stations and has offered the use of the stations and equipment rent free up to Jan. 1st next.

Enlargement of St. Luke's Hospital, New York.

An out-patient department building for St. Luke's Hospital, New York, was opened on Oct. 19th. It cost $250,000 (£50,000), the amount having been bequeathed by the late Mr. John G. Hecksher.

Death of Dr. Alexander Hugh Ferguson, of Chicago.

Dr. Alexander Hugh Ferguson died from blood poisoning at his home on Oct. 20th. He was born in Ontario, Canada, on Feb. 27th, 1853, and was therefore 58 years of age. He took his M.D. degree in the Medical College of Trinity University, Toronto. After study-travel in Europe, he settled in practice in Winnipeg in 1881, where he founded the Manitoba Medical College, at which he was professor—first of physiology and subsequently of surgery. Going to Chicago in 1894, he became professor of clinical surgery in 1900 at the College of Physicians and Surgeons there. He became surgeon to the Post-Graduate Hospital and Cook County Hospital for the Insane, and surgeon in chief to the Chicago Hospital. He was a member of the British Medical Association, the American Medical Association, the International Surgical Association, and a Fellow of the Chicago Academy of Medicine, as well as of many other medical societies.

Oct. 28th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE mortality from plague in India during the week ending Sept. 23rd amounted to 6668 deaths, of which Bombay Presidency accounted for 4748 deaths. In other provinces the figures were as follows: Madras, 583 deaths; Bengal, 18; the United Provinces, 42; the Punjab, 5; Burma, 17; and the Central Provinces, 379. There were 546 and 189 fatal cases in Mysore and Central India respectively.

A Consumption Sanatorium.

The foundation-stone of the Hardinge Consumptive Hospital at Dharampur (Simla Hills) was laid by the Viceroy on Oct. 4th. The Maharaja of Patiala has sanctioned Rs. 60,000 for the building of the hospital. The building will consist of (1) an out-patient department and dispensary room; (2) indoor wards; (3) large operation room, with anæsthetising room; (4) bacteriological and chemical analysis rooms, with apparatus even for spectrum examination of blood, urine, &c., and for carrying out opsonic index examination. At present there are to be eight male and four female wards, but cottages will be erected as funds permit and the demand arises. The main building is on the pavilion system with ample verandah accommodation for patients in all weathers. There will be accommodation for a resident assistant surgeon, two sub-assistant surgeons, and a compounder. This is the first sanatorium of its kind in the East.

Panama Canal and Yellow Fever.

Major S. P. James, I.M.S., statistical officer to the Government of India, goes on deputation for ten months to Panama and the West Indies to study yellow fever in the endemic area and so advise the Government as to the measures which are necessary to prevent the disease spreading to India when the Panama Canal is opened. He leaves Simla on Oct. 23rd and goes to the Straits, thence to Hong-Kong (to attend the International Conference on Tropical Medicine), after which he proceeds *viâ* Hawaii to Panama (where he spends three months), afterwards visiting the West Indies. Captain A. G. McKendrick, I.M.S., acts for him in his absence.

The Medical Registration Act of Bombay.

The Bombay Medical Act of 1911 (Bill VI. of 1911) is

now published and is for consideration by the Legislative Council. It extends only to the Bombay Presidency. The Council is to consist of 13 members, as follows: (*a*) a president nominated by the Governor; (*b*) six members nominated by the Governor; (*c*) four members nominated by graduates of the University of Bombay; and (*d*) two members elected by the medical practitioners practising in Bombay. No person is eligible to be a member of the Council unless he is a member of one of the services or is a graduate or licentiate of the University of Bombay. This clause excludes an independent medical practitioner of any nationality or of any European college or university, and is an injustice which requires amendment. The members of Council are to be elected for a term of five years. £1 is the fee for registration. A person convicted of grave unprofessional conduct may be removed from the Register. No medical certificate is to be valid, except that of a medical man on the Register. No one can hold a hospital or other public medical appointment unless he is on the Register. Every registrar of deaths has to inform the registrar of the Council of the death of a practitioner on the Register. All examining bodies have to furnish any information required of them by the Council. Any attempt to give false information to the registrar is punishable by a fine of 300 rupees. The Council may make rules as to any examination. The objects of the Bill are to protect the public against irregularly qualified practitioners, and to ascertain if practitioners have certain recognised qualifications stated in the schedule. It places no direct restriction upon the practice of Indian vaids and hakims, but will improve the status of those practising the Western medical art. It places no obstacle on the recovery of fees by unregistered persons. In this respect it is weak.

Oct. 8th.

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Alabama Medical College:* Dr. William F. R. Philips has been appointed to the chair of Anatomy.—*Berlin:* Dr. Edmund Lesser, Director of the Dermatological Clinic, has been promoted to be Ordinary Professor of Dermatology.—*Bonn:* Dr. Ludwig Tobler, of Heidelberg, has been offered an Extraordinary Professorship of Children's Diseases.—*Düsseldorf (Academy of Practical Medicine):* Dr. Emil Ballowitz, Professor of Anatomy in Münster, has been appointed to the chair of Topographical Anatomy.—*Göttingen:* Dr. Creite, *privat-docent*, has been appointed Director of the Surgical Side of the Policlinic in succession to Dr. J. Rosenbach, retired.—*Marburg:* Dr. M. Heyde has been recognised as *privat-docent* of Surgery.—*Munich:* Dr. Seydel, Professor in the University and Director of the Academy of Military Medicine, has been appointed Staff-Surgeon-General of the Bavarian Army in succession to His Excellency General von Bestelmeyer, who is retiring.—*Padua:* Dr. G. A. Pari has been recognised as *privat-docent* of Medical Pathology, and Dr. C. Finzi as *privat-docent* of Midwifery and Gynæcology.—*Palermo:* Dr. Cesare La Rocca has been recognised as *privat-docent* of Anatomy, Dr. Fausto Orestano as *privat-docent* of Operative Medicine, Dr. Giuseppe Spagnolio as *privat-docent* of Medical Pathology, Dr. Di Cristina Giovanni as *privat-docent* of Pædiatry, and Dr. Menotti Iorfida as *privat-docent* of External Pathology.—*Pavia:* Dr. F. Strada has been recognised as *privat-docent* of Pathological Anatomy and Histology, and Dr. Verga as *privat-docent* of External Pathology.—*Rome:* Dr. G. Garbini has been recognised as *privat-docent* of Psychiatry.—*Vienna:* Dr. Otto Porges has been recognised as *privat-docent* of Medicine.

ASYLUMS IN DIFFICULTY.—Owing to all the county asylums in Lancashire being crowded the Lancashire asylums board found it imperative to construct a new asylum, and Walley was fixed on as a site as early as 1902. Since then opposition from the residents of the district and delay in passing the plans by the Commissioners in Lunacy prevented a start being made with the work until a year ago, when the contract was let to a large building firm for £355,846. It was expected that it would take three and a half years to complete the building, of which less than one-third has been constructed during the past year. It has just been officially announced at Preston by the Lancashire asylums board that the contractors have paid off their men and stopped the work of building the asylum. The Derbyshire county council decided to build a large lunatic asylum in the Hope Valley to accommodate 800 inmates at a cost of £240,000. Some opposition has been offered by some of the residents, but the county council intends to persevere with the scheme and carry it through.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The lectures before the College for next year are, as at present arranged, as follows: Goulstonian, Dr. H. G. Adamson; Lumleian, Dr. Percy Kidd; Croonian, Mr. L. S. Dudgeon; Milroy, Dr. F. A. Bainbridge; Horace Dobell, Dr. C. J. Martin; Fitz-Patrick, Dr. Raymond Crawfurd; Oliver-Sharpey, Sir Ronald Ross.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the annual general meeting of the Fellows and Members of the Royal College of Surgeons of England on Thursday next Dr. Joseph Smith, President of the above society, will move a resolution affirming the desirability of admitting Members to direct representation on the Council.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Dr. E. Slack, medical officer, Gold Coast, has resigned, and Dr. C. S. Thompson, medical officer, Southern Nigeria, has retired. Mr. A. G. Eldred, medical officer, Gold Coast, has been transferred to the Nyasaland Protectorate. The following officers have been promoted: Dr. J. A. Clough, medical officer, Southern Nigeria, to be a senior medical officer, Gold Coast; Mr. J. W. Collett, medical officer, Southern Nigeria, to be senior medical officer, Sierra Leone; Mr. C. F. Watson, medical officer, Northern Nigeria, to be a senior medical officer, Northern Nigeria; and Dr. W. H. A. Gordon-Hall, medical officer, Northern Nigeria, to be a senior medical officer, Northern Nigeria. The following have been selected for appointment to the staff: Dr. E. C. Braithwaite (Southern Nigeria), Dr. B. J. Courtney (Northern Nigeria), and Dr. H. R. M. Ferguson (Southern Nigeria). *Other Colonies and Protectorates:* The following have been selected for appointment: Dr. A. Barber, as a medical officer in the Straits Settlements; Dr. G. E Craig, as a medical officer in British Guiana; Dr. F. W. Falconer, as a house surgeon in the Federated Malay States; Dr. A. Mathieson, as a medical officer in the Straits Settlements; Dr. R. F. Priestley, as a medical officer with the work of a house surgeon in the Straits Settlements; Dr. S. P. Proctor, as a supernumerary medical officer in Trinidad; and Dr. C. J. Smith, as a house surgeon in the Federated Malay States.

A HEALTH CONFERENCE AND EXHIBITION.—A biennial conference and exhibition is to be held under the patronage of Her Royal Highness Princess Christian of Schleswig-Holstein at the Horticultural Hall, Westminster, on June 24th, 25th, 26th, and 27th, 1912. The conference, which will extend over the four days, will deal with (1) the health of infants; (2) the health of boys and girls; (3) public health; and (4) the care and cure of the sick; and it and the exhibition are intended to appeal to all classes. Opportunity will be given for the discussion of the higher technical and scientific subjects connected with public health, but the chief aim is to illustrate the simple practical methods of hygiene and sanitation which are attainable by even the humblest households, if only the inmates are willing and anxious, by regarding elementary principles, to insure good health to themselves and their children, and by this means to help toward maintaining a sound and healthy race. The coöperation of all public health bodies and officials, as well as local health organisations, throughout the country, is being sought. Among the exhibits will be cookery demonstrations, first aid and home nursing, crèche life, a model home and how to clean it, healthy occupations for boys and girls, and the methods whereby a knowledge of simple domestic hygiene may be applied to everyday life. Representatives of health organisations are invited to communicate with the promoter and organising secretary to the conference and exhibition, Miss R. V. Gill, and to suggest any subjects for discussion, and to offer any advice upon the methods which may be adopted to ensure the practical utility of the exhibition. Space will be allotted to

the exhibits of philanthropic bodies and workers in order that every opportunity may be afforded to give publicity to such work as may benefit the community. Communications relating to the conference and private exhibits should be addressed to Miss Gill; communications regarding trade exhibits to the business manager, Mr. Frank Virgo, at 35, Ludgate-hill, London, E.C.

Apollinaris Water has received the Grand Prix at the Dresden Exhibition.

MEDICAL MAGISTRATE.—The Lord Chancellor has appointed Mr. Carey Pearce Coombs, M.D. Lond., M.R.C.S. Eng., of Castle Cary, a justice of the peace for the county of Somerset.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the meeting of the President and Fellows of the Royal College of Physicians of Ireland held on Nov. 3rd, Mr. Charles Greer, F.R.C.S.I., was admitted to the Membership of the College and Mr. R. J. Cyriax and Dr. L. S. Modi were admitted Licentiates in Midwifery.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The council of this school has appointed Dr. Walter d'Este Emery to be Lecturer in General Pathology, and Dr. W. H. B. Stoddart to be Lecturer in Mental Pathology.—The St. Dunstan's trustees have awarded an Exhibition, tenable at the Medical School, to Miss N. Gibson, and a special grant to Miss Joyce B. Reed. The School Scholarship has been awarded to Miss Joyce B. Reed.—The Mabel Webb Research Scholarship has been awarded to Miss C. Leetham, who will carry out research in physiology in the Physiological Department.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. C. J. Auffret, formerly Inspector-General of the French Army Medical Service.—Dr. Caspary, formerly professor of dermatology in Königsberg.—Dr. Max Jaffe, professor of pharmacology and medical chemistry in the University of Berlin, aged 70. He was the author of many original papers on pharmacological subjects, and enjoyed a very extensive practice, patients coming to him from Russia and other foreign countries. His advice, too, was constantly sought by Berlin practitioners, amongst whom he was very popular.—Dr. Getto, who is supposed to be the Nestor of German medical men, has died at Deidesheim, aged 98.—Dr. A. W. C. Berns, of Utrecht, aged 74, who during the Franco-German War established a hospital at Düsseldorf for the sick and wounded, and was afterwards a professor in Freiburg. In his youth he had been a minister in Holland, where he was born and educated both for the Church and for medicine, taking his medical degree in Utrecht in 1869. He returned to Holland in 1876, and practised for several years in Amsterdam.

NOTES ON CURRENT TOPICS.

National Insurance Bill.

THE House of Commons continues to make steady progress with the National Insurance Bill under the closure resolution. The debates are proceeding with greater smoothness than was anticipated at the commencement of the autumn session. Many of the clauses which are now being disposed of contain technical details of machinery. The principal points of controversy in which the medical profession are closely concerned will, it appears, not be reviewed until the report stage. Mr. MCKINNON WOOD, who as Secretary to the Treasury is acting on behalf of the Chancellor of the Exchequer at question time, has stated that points of detail arising out of the decision of the Committee concerning the relations between the Friendly Societies and the medical profession have been under discussion and will be dealt with on report.

On Tuesday, Nov. 7th, the House of Commons had before it the amended proposals of the Government with regard to the inclusion of soldiers and sailors within the provisions of the National Insurance Bill. The weekly deduction from pay is to be 1½*d*. Maternity benefits will be given to the wives of soldiers and sailors. Men who have been members of approved societies are to have their contributions credited to their own societies, and this will enable the societies to admit them when discharged to full benefits. Men who do not join societies will be allowed to be members of a Navy and Army Insurance Fund. Although no charge for sanatorium benefit will be made upon the contributions in respect of men while serving, it is intended that such men should, if they contract tuberculosis during service be given treatment in the sanatoriums provided under the scheme, and that the cost of such treatment should be borne by Army and Navy votes.

Owing to the time absorbed by the discussion of the scheme for soldiers and sailors, no opportunity was available before the closure resolution took effect to consider the details of Clauses 41 and 42. Clause 41 relates to the constitution of the Insurance Commissioners, but on the motion of Mr. LLOYD GEORGE it was amended so as to provide that one of the Commissioners at least should be "a duly qualified medical practitioner who has had personal experience of general practice."

Clause 42 sets up an Advisory Committee for the purpose of giving the Insurance Commissioners advice and assistance in connexion with the making and altering of regulations. It was originally proposed that the committee should consist of "representatives of associations of employers and approved societies and of such other persons as the Commissioners may appoint." By an amendment proposed by the Chancellor of the Exchequer, "duly qualified medical practitioners who have personal experience of general practice" are included specifically amongst the categories of persons to be appointed to the Advisory Committee.

A very vigorous protest was entered in the House of Commons on Wednesday, Nov. 8th, on the relatively smaller representation of the Local Health Committees which Mr. LLOYD GEORGE's new proposals give to the medical profession. As amended Clause 43 (appointment of Local Health Committees) provides that—

"Such number of the members of the committee as the Insurance Commissioners having regard to the circumstances of each case determine (but in no case less than 24 or more than 48) shall be appointed in such manner as may be prescribed by regulations of the Insurance Commissioners so as to secure representation of the insured persons resident in the county or county borough who are members of approved societies, and who are deposit contributors in proportion, as nearly as may be, to their respective numbers; and the regulations so made shall provide for conferring on the approved societies which have members resident in the county or county borough the power of appointing the representatives of such members, and, where an association of the deposit contributors resident in the county or county borough has been formed under such regulations as aforesaid for conferring on such association the power of appointing the representatives of the deposit contributors.

2. Of the remaining members of the committee, who shall not exceed two-thirds of the number of members appointed in manner aforesaid, one-half shall be appointed by the council of the county or county borough, two shall be elected in manner provided by regulations made by the Insurance Commissioners, either by any association of duly qualified medical practitioners resident in the county or county borough which may have been formed for that purpose under such regulations, or if no such association has been formed by such practitioners, and the others shall be appointed by the Insurance Commissioners.

Provided that the members appointed by the council of the county or county borough shall consist wholly or in part of members of the local sanitary authorities and two at least shall be women, and of the members appointed by the Insurance Commissioners one at least shall be a duly qualified medical practitioner and two at least shall be women.

3. The Insurance Commissioners may, where any part of the cost of medical benefit or sanatorium benefit is defrayed by the council of the county or county borough, increase the representation of the council and make a corresponding diminution in the representation of the insured persons."

The effect of this change is to increase greatly the standard of numbers on the Local Health Committees, and to give the preponderating control in them to the Friendly Society element. There is no corresponding increase in the medical representation. Before the change was made Sir PHILIP MAGNUS described it as a "betrayal" of the interests of the medical profession. Sir ROBERT FINLAY regarded it as the re-introduction of the Friendly Society control which was acutely resented by the doctors. Mr. LLOYD GEORGE denied that there was any breach of faith involved in giving a majority to the insured persons, but Sir ROBERT FINLAY declared that the right honourable gentleman would not have satisfied the medical profession if it had had the new scheme before it. The Chancellor's amendment was carried. The Government has indicated its readiness to adopt the designation "Insurance Committee" instead of "Local Health Committee."

HOUSE OF LORDS.

THURSDAY, NOV. 2ND.

The Indian Sanitary Commissioner.

Earl CURZON, in the course of a speech raising several points in regard to Indian administration, asked the Secretary of State for India what decision he had come to in respect to the reported decision of the Government of India to abolish several superior offices. Amongst those offices was that of the Sanitary Commissioner.

The Marquis of CREWE, in the course of his reply, said that the question of centralisation or of provincialism was not involved as regarded the Sanitary Commissioner. The proposal submitted to him in this case was that instead of having a director-general of the medical

service and a commissioner of sanitation, to throw these offices once more under one head, and to give the director-general of medicine full charge of sanitation. As to this, he thought, with the full agreement of the Indian Council, that it was desirable to retain the Sanitary Commissioner, but as regarded his precise relations with the Director-General of the Indian Medical Service, he had asked the Government of India to reconsider the question with a view to come to a decision as to what exactly those relations ought to be. It had been found that a complete separation of sanitation and medical research from the practical and clinical side of medicine had created a good deal of difficulty, and had tended to make the research side unpopular with the young men who wished to keep their general information alive. They said that it was necessary for them to have some chance of watching the processes of applied science, and that if they had not a chance of doing so they were in no better position than if they were in the laboratory of some maker of patent medicines or preparer of drugs in the form now so popular. They had not the chance of improving themselves in the general knowledge and practice of their profession so long as research was carried on—as the tendency had been to carry it on far away from large hospitals and the means of studying cases. It was therefore desired that the medical and bacteriological and sanitary sides should be more closely brought together. He thought that that was an argument which demanded consideration, and had therefore asked the Government of India to consider carefully what the relations of the Sanitary Commission, as it existed, ought to be to the Director-General of the Medical Service.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 1ST.

The Medical Profession and the National Insurance Bill.

Mr. AMERY asked the Secretary to the Treasury whether the Chancellor of the Exchequer had now successfully adjusted the outstanding points of difference with the medical profession on the National Insurance Bill; and when amendments dealing with these points would be put on the paper.—Mr. MCKINNON WOOD replied: So far as I am aware, the most important amendments affecting the medical profession were dealt with by the Committee on Clause 14. Points of detail arising out of the decision of the Committee concerning the relations between the societies and the medical profession have been under discussion, and will be dealt with on report.

National Insurance Topics.

Mr. AMERY asked the Secretary to the Treasury in what manner the medical benefit, due to the end of the current year, would be administered in the case of a deposit contributor who after suspension from sick benefit has become an inmate of a workhouse infirmary.—Mr. MCKINNON WOOD answered: The Local Health Committee will place the services of a doctor at the disposal of any insured person who is for the time being entitled to medical benefit.

Mr. AMERY: Will not a person in that case already receive medical attendance gratis from the workhouse authorities?—Mr. MCKINNON WOOD: Probably he would.

Mr. AMERY: In that case what advantage would medical benefit be, and would the value of the medical benefit given to the individual be credited to the Post Office Fund in general.—Mr. MCKINNON WOOD: I think it would be credited to the Post Office Fund in general. He would be receiving medical treatment in another form under the Poor-law.

Mr. GODFREY LOCKER-LAMPSON asked the right honourable gentleman what arrangements would be made for the provision of medical attendance upon an insured person who happened to fall ill outside the district covered by the panel of doctors who attended upon the members of the approved society to which he belonged.—Mr. MCKINNON WOOD replied: The honourable Member is under a misapprehension in supposing that a panel of doctors will be appointed for an approved society. The panel will be appointed for the area of a Local Health Committee. The administrative details necessary to provide for the temporary or permanent migration of insured persons from one such area to another can be dealt with by the regulations to be made by the Insurance Commissioners under Clause 14.

Mr. G. LOCKER-LAMPSON also asked whether any steps would be taken to utilise existing provident dispensaries under the National Insurance Bill.—Mr MCKINNON WOOD said in reply: I am unable to give a general answer to this question. The matter will depend to a large extent on the use made in each case by the Local Health Committees and Insurance Commissioners of their powers under Clause 14 (4).

Sir J. LONSDALE asked whether dispensary medical officers in Ireland who were required under the National Insurance Bill, Clause 59, to attend and treat deposit contributors in their area would be remunerated upon the same scale as medical practitioners with whom arrangements were made by the Local Health Committee; and if it would be practicable under this Bill to provide for the superannuation of dispensary medical officers on attaining the age of 65 years.—Mr. MCKINNON WOOD answered: Clause 59 does not require the same scale to be prescribed in the two cases specified. It would not be possible to provide under the National Insurance Bill for the superannuation of dispensary medical officers.

Mr. CATHCART WASON asked the Lord Advocate whether the Scotch Office had brought before the Chancellor of the Exchequer the position of deposit contributors in the Highland and Islands, and of the fact that under the Bill as it stood in many cases the deposit contributors would have no opportunity of availing themselves of the medical benefits of the Bill; and whether he would use every legitimate influence in his power to obtain a special grant to enable medical officers to visit far distant patients.—Mr. URE answered: I can assure my honourable friend that the matters to which he refers are under consideration.

Sanitary Condition of Osborne College.

Mr. DOUGLAS HALL asked the Civil Lord of the Admiralty whether his attention had been called to the complaints with regard to the sanitary condition of certain parts of Osborne College; and whether he would consider the advisability of rebuilding the portions of the College which were unhealthy.—Mr. G. LAMBERT replied: The question of replacing the temporary buildings now used by buildings of a more permanent nature is at the present time engaging the attention of the Admiralty. But I cannot admit the suggestion that the existing buildings are injurious to the health of the cadets.

Lord CHARLES BERESFORD: Is it not a fact that there have been very serious epidemics at Osborne on many occasions?—Mr. LAMBERT: Yes, there have been epidemics, but they have been brought in from the outside. Boys are brought into Osborne about the age of 13, when they are peculiarly subject to these epidemics—mumps, measles, and such like.

Lord CHARLES BERESFORD: Has it not been officially reported by the officers at Osborne College that the College is unhealthy?—Mr. LAMBERT: No, I have not heard of it.

Naval Sick Berth Staff.

Lord CHARLES BERESFORD asked the Secretary to the Admiralty whether he was aware of the discontent amongst all ratings of the naval sick berth staff, and whether he would inform the House why an attendant looking after a mild case of measles received an allowance of 6*d.* a day, yet an attendant carrying out the risky work of looking after a lunatic only received an allowance of 4*d.* a day, a dispenser was only awarded an allowance of 2*d.* a day, looking to the fact that his duties during the influenza season in the North Sea or in the fever months in the Mediterranean were very heavy, and the allowance to men qualified in massage had been reduced from 1*s.* to 6*d.* a day.—Mr. MACNAMARA said, in reply: The various allowances were adopted on the recommendation of the recent committee on the Naval Medical Service, and were graded with due regard to the value, difficulty, danger, &c., of the particular work for which allowance is given.

Sisters in the Naval Medical Service.

Lord CHARLES BERESFORD asked the Secretary to the Admiralty whether a new rank of Superintending Sister had been instituted; whether he would state to the House the total number of sisters in the Naval Medical Service; whether he was aware that seven sisters had been promoted over the heads of their seniors; whether he would state the seniority of the four superintending sisters appointed to the Home hospitals, and also the three superintending sisters appointed abroad; whether, out of the seven superintending sisters selected, four had done no foreign service and the other three had not yet completed a first commission abroad; and whether he had any reason to believe that a selection of this character would create a sense of unfairness amongst the sisters of the Naval Medical Service.—Mr. MACNAMARA said, in reply: The total number of sisters in Queen Alexandra's Royal Naval Nursing Service is 70, inclusive of three head sisters and seven newly appointed superintending sisters. The superintending sisters had seniority in the rank of sister as from Feb. 1st, 1905, June 1st, 1905, May 1st, 1906 Dec. 23rd, 1908, Jan. 2nd, 1909, Jan. 11th, 1909, and Jan. 18th, 1909, respectively. Four of them have not yet served abroad, and the other three had not completed a normal term of foreign service at the date of their promotion. As a result of the most careful consideration the Board found it necessary in making these promotions to pass over a number of sisters who, although qualified to perform their present duties satisfactorily, were not fitted for the discharge of the more important administrative duties devolving on a superintending sister.

Care of the Feeble-minded.

Dr. CHAPPLE asked the President of the Local Government Board whether his attention had been drawn to the resolution of the National Association for the Feeble-minded urging the Government to pass a Bill making the permanent segregation of the feeble-minded compulsory; and whether in the interests of these defectives themselves, for the sake of sufferers still unborn, and for the relief of the community from the ever-increasing burden of the taxation paid by the fit for the support of the unfit, he would bring in a Bill to give effect to this resolution.

Mr HICKS-BEACH asked the Prime Minister to say when His Majesty's Government proposed to give effect to the report of the Royal Commission on the Care and Control of the Feeble-minded, issued three years ago, by bringing forward a measure to carry out its recommendations.—Mr. ASQUITH replied to both questions: I have every hope that legislation dealing with this question will be undertaken next session.

THURSDAY, NOV. 2ND.

Irish Dispensary Doctors and the National Insurance Bill.

Sir J. LONSDALE asked the Chief Secretary to the Lord Lieutenant of Ireland to state the number of medical officers, dispensary and workhouse, in the Poor-law service in Ireland who were aged 65 years and upwards; and whether, having regard to the additional work, entailing severe physical exertion, which would devolve upon dispensary medical officers under the provisions of the National Insurance Bill, it was intended to frame proposals for the superannuation of those officials who had passed the age of 65.—Mr. BIRRELL replied: The information desired is not directly available and could only be obtained by searching through the original appointment of all the medical officers in Ireland. A clause respecting superannuation of dispensary medical officers would hardly be germane to the National Insurance Bill.

Local Provident Medical Associations.

Mr. SANDYS asked the Chancellor of the Exchequer, what would be the position under the National Insurance Bill of a local provident medical association providing medical attendance for about 1600 members resident in the district at a small weekly payment.—Mr. LLOYD GEORGE wrote in reply: I would refer the honourable Member to Clause 14 (4), which makes provision for utilising such associations in certain circumstances for the purposes of medical benefit under the Bill.

Vaccination in Scotland.

Mr. BARNES asked the Lord Advocate whether there was any specified number of marks required by the Scottish Local Government Board for the efficient vaccination of children, and, if so, how many; whether he was aware that children of poor people who were vaccinated gratuitously at the Sanitary Chambers, Glasgow, were vaccinated in 12 places, and, if so, would he take steps to put a stop to the practice and to make it more conform to the practice observed by private medical practitioners; and whether he would state if vaccination operations at the Sanitary Chambers, Glasgow, were performed exclusively by duly qualified medical practitioners, and, if not, by whom.—Mr. URE answered: I am informed that the Scottish Local Government Board

does not specify the number of marks required for the efficient vaccination of children. It is aware that children are vaccinated gratuitously at the Sanitary Chambers in Glasgow, and that all primary infantile vaccinations are performed there by duly qualified medical practitioners. The Board is further informed that it is the case that 12 separate punctures are made in primary vaccination of infants, such punctures being very close together. A general description of the method of vaccination in the Sanitary Chambers, Glasgow, will be found at p. 19 of Appendix VIII. of the final report of the Royal Commission on Vaccination, 1897.

Asylum Officers' Superannuation Bill.

Mr. ASQUITH, in the course of a written answer, informed Mr. NIELD that he was afraid that there was no reasonable prospect of the Asylum Officers (Employment, Pensions, and Superannuation) Bill being passed into law during the present session.

Vaccination in the Army.

Mr. JOHN WARD asked the Under Secretary of State for War whether he could give the number of men, recruits or otherwise, in the British army at home or abroad who went into hospital on account of vaccination or revaccination, or sickness consequent on vaccination or revaccination, in the years 1900 to 1910.—Colonel SEELY furnished the following written reply: No statistics prior to 1907 are available. The figures for subsequent years are as follows:—1907, 379; 1908, 316; 1909, 284; 1910, 379.

Mr. POINTER asked the Under Secretary of State for War whether he could explain the statement on p. 41 of the Annual Report of the Sanitary Commissioner with the Government of India for 1909 that none of the women with the European troops in India who were attacked by small-pox during the year 1909 had been revaccinated, in view of the statement on p. 203 of the Army Medical Department Report for 1906 that in October of each year all men, as well as women and children, were inspected, and those revaccinated who did not show either satisfactory marks or records of vaccination; and whether, if the women in question were, in fact, not revaccinated, he would state how it was that they escaped the operation at the last annual inspection of their vaccinal condition.—Colonel SEELY wrote in reply: It may be presumed that at the vaccination in question no renewal of vaccination was considered necessary either because the women bore marks which were considered satisfactory marks of vaccination or because there was a record of revaccination in their cases.

Vaccination in Eastbourne.

Mr. RUPERT GWYNNE asked the President of the Local Government Board whether, after the lapse of ten years, summonses against defaulters under the Vaccination Acts had been obtained at Eastbourne by the vaccination officer through the pressure of the Local Government Board; whether there had been any case of small-pox in the town during that period; what was the total number of children in the town legally exempted from vaccination under the Vaccination Acts, 1898 and 1907, and what special circumstances, if any, prompted the action of the Board.—Mr. BURNS wrote in reply: It is the duty of the vaccination officer to take proceedings to secure compliance with the Vaccination Acts, and the Board's inspector, at his last inspection of vaccination in this union, reminded him of this duty. The Board understands that the vaccination officer has recently obtained summonses against certain persons who have not complied with the Acts. During the last ten years there have been two cases of small-pox in Eastbourne. The total number of children in the Eastbourne Union who have been legally exempted from vaccination from the time of the passing of the Vaccination Act, 1898, to July 31st, 1911, is, according to the Board's records 5640. Some five-sixths of these have been children residing in the town of Eastbourne.

MONDAY, NOV. 6TH.

Patent Medicines.

Mr. CHARLES BATHURST asked the Secretary to the Treasury whether the Customs and Excise Returns for the year ended March 31st, 1911, disclosed payment of stamp duties in respect of patent medicines of upwards of £325,000; if so, whether this represented an increase, and to what extent, on the amount of the duties paid under the same head during the previous financial year; what number of packages of patent medicines the above duties represented, and whether, in view of the amount of such medicines widely advertised and of no curative value consumed by poor persons, the Government contemplated introducing any legislation dealing with this question.—Mr. MCKINNON WOOD replied: The yield on the duty on patent medicines in the year ended March 31st last was £325,646, which was an increase of £12,532 on the receipt for the previous year, but is little more than £2000 over the average receipts for the past ten years. No figures are available as to the number of packets of medicines represented by the figures for the year. The last part of the question appears to be one for the Home Office.

Sanatorium Benefit.

Mr. KING asked the Secretary to the Treasury whether he had had under consideration the results of recent actuarial investigations carried out in the Francis Galton Laboratory of the University of London into the falling death-rate from phthisis and the length of life of sanatorium patients; and, if so, whether, before sanctioning the expenditure of many thousands of pounds on the erection of sanatoriums, he would cause a fresh actuarial inquiry to be made as to the effectiveness of sanatorium treatment.—Mr. MCKINNON WOOD said in reply: The right honourable gentleman is satisfied that "sanatorium benefit," as defined in the National Insurance Bill, which is capable of modification in accordance with the growth of medical experience, comprises the best known means for treating tuberculosis and of aiding in preventing its spread.

Medical Benefits in the Highlands.

Mr. CATHCART WASON asked the Secretary to the Treasury whether, in view of the fact that in many places in the Highlands and Islands of Scotland it would be impossible for deposit contributors to obtain medical benefits under the Insurance Bill, he would allow the Local Government Board for Scotland power to apportion that part of the Scottish money available for the Highlands and Islands for more general purposes than sanatoriums, such as increase of medical service, grants in aid of travelling expenses of medical men attending insured persons, provision of hospital accommodation, and removal of insanitary conditions in places where the public health rate was at the legal maximum.—Mr. MCKINNON WOOD answered: I trust that it may prove to be possible to provide medical benefit for all deposit contributors, and some of the expenses which my honourable friend specifies could under the Bill as it stands be properly incurred by the Local Health Committees. I fear it would not be possible to provide for the application of funds contributed under the Bill directly to the removal of insanitary conditions.

TUESDAY, NOV. 7TH.

Cholera Outbreak in India.

In answer to Mr. MITCHELL-THOMSON, who asked for information regarding the outbreak of cholera in the 1st Battalion Royal Scots, Mr. MONTAGU (Under Secretary of State for India) said: The following telegram was received by the Secretary of State for India from the Governor-General on Nov. 4th:—"Outbreak of cholera in 1st Battalion Royal Scots. Total cases up to date 25, deaths 10. It was explosive outbreak, occurring suddenly on Nov. 1st, due to infection acquired in Benares city, where it was prevalent and aggravated by inrush of pilgrims on account of recent eclipse. Troops moved to camp. Outbreak at once checked, now well in hand and probably over."

The Office of Public Vaccinator.

Mr. CRAWSHAY-WILLIAMS asked the President of the Local Government Board whether his attention had been called to the opinion of Dr. Killick Millard, medical officer of health of Leicester, that the future control of small-pox lay with the medical officer of health rather than with the public vaccinator; and whether the Board was prepared to allow the position of public vaccinator to lapse as vacancies arise.—Mr. BURNS replied: My attention has been drawn to the opinion attributed to this particular medical officer of health. I am not at present proposing any alteration in the position of the office of public vaccinator.

National Insurance Bill Topics.

Mr. H. HOPE asked the Secretary to the Treasury whether doctors in popular holiday resorts would receive remuneration for attending persons insured under the National Insurance Bill who were on holiday in such places.—Mr. MCKINNON WOOD replied: The question will be one to be dealt with by the regulations to be drawn up under Clause 14.

Mr PRETYMAN asked the Chancellor of the Exchequer whether the surgery of a country doctor required to dispense under the National Insurance Bill would become liable to inspection under the provision of the Food and Drugs Act.—Mr. LLOYD GEORGE wrote in reply: There is nothing in the Insurance Bill to alter the existing position of doctors' dispensaries in this respect.

Sir WALTER MENZIES asked the Chancellor of the Exchequer whether he could see his way to introduce a clause into the National Insurance Bill providing that insured persons who had lost faith in, or had conscientious objections to, orthodox medical treatment might be allowed to consult unregistered medical practitioners, such as herbalists, &c., if they so desired; and would such unregistered practitioners be allowed on the panel for the district.—Mr. LLOYD GEORGE wrote in reply: I would refer my honourable friend to the provisions of Clause 14 (3) of the Bill as amended in Committee. As regards the second question the answer is in the negative.

BOOKS, ETC., RECEIVED.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A MYSTERIOUS REFORM.

AN anonymous correspondent has sent us a postcard inscribed as follows:—

TWO REFORMS URGENTLY NEEDED.

1st. *Allopathic* Medical Students to refrain from *Rowdyism*.

2nd. *Allopathy* to be abolished, and Medical Botany to take its place. *Allopathy is nothing but a curse. It has murdered millions.*

While we feel that entertaining views of this sort should not be confined to the columns of the *Herb Doctor*, we wish that those who hold and preach them would explain what exactly they mean by the queer word "allopathy." If we knew what was the curse that ought to be abolished, we might lend our support to the reformers. Alligators, ally tors, and alibis are quite familiar to us, and so is medical botany, which we believe some students would like abolished from the second professional examination. We can find no reference to "allopathy" in the "Encyclopædia Britannica," and we are forced to conclude that the postcard was really intended for a non-medical contemporary whose name begins with Alley.

"LOCOMOTION ATAXIA."

THE following ingenious couplet appears in this week's *Truth*:—

"Occupet urbanas, ceu morbus, ataxia raedas:
Res bona dumtaxat, nec male pestis olet."

INSTRUCTION FOR PUPIL MIDWIVES.

A MEDICAL man wishes to learn of an inexpensive course of instruction in midwifery for the licence of the Central Midwives Board. Inquiry at one lying-in hospital showed that the charge for five months would be £35, which is beyond the means of our correspondent.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Nov. 1st–14th (London).—"The Englishwoman" Exhibition of Arts and Handicrafts.
,, 3rd–11th (London, Olympia).—Tenth International Motor Exhibition.
,, 9th–11th (Cape Town).—Congress of the South African Branch of the Royal Sanitary Institute.
,, 10th–25th (Manchester).—Smoke Abatement Exhibition.
,, 14th and 15th (Vienna).—Jubilee of Union of Austrian Dental Surgeons.
,, 21st–23rd (Montreal).—Canadian Public Health Association (First Annual Meeting).
November (Rome).—Fourth International Congress of Physical Education.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
,, 19th–23rd (Moscow).—Third Pan-Russian Therapeutical Congress.

In 1912:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
March (London).—First Congress of Pure Food and Health Society of Great Britain.
,, (Berlin).—Thirty third Balneological Congress.
April 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.
May 27th–June 1st (London).—Eighteenth International Congress of Americanists.
,, (London).—International Horticultural Exhibition.
June 24th–27th (London).—The (Biennial) Health Conference and Exhibition.
June (London).—Missionary Exhibition.
July 2nd–5th (London).—Congress of the Universities of the Empire.
,, 2nd–6th (Doncaster).—Seventy-third Annual Show of the Royal Agricultural Society of England.
,, 12th–16th (London).—Imperial Conference of Teachers' Associations.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—L. A. Dunn, James Berry): at 5.30 P.M.

Opening Remarks by the President, Mr. Clinton T. Dent.

Dr. Ringrose Gore: Case of Caries of Frontal Bone and Intracranial Abscess due to B. Typhosus 11 Years after Attack of Typhoid.

Mr. H. Betham Robinson: Extra-peritoneal Rupture of the Bladder without Fracture of the Pelvis.

Mr. L. A. Dunn: Retrograde Enteric Intussusception.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfred Fox), at 11, Chandos-street, W.: at 5 P.M.

Dr. J. L. Bunch: (1) Urticaria Pigmentosa; (2) Atrophic Seborrhoid; (3) Multiple Angiomata.

Dr. Sequeira: Extensive Ringworm.

And other Cases.

SPECIAL MEETING at 15, Cavendish-square, W.: at 8.30 P.M.

Discussion

On Eczematoid Ringworm of the Extremities and Groin (opened by Dr. A Whitfield).

Dr. Sabouraud (Paris) will take part in the Discussion.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Sydney Scott, A. Logan Turner), at 11, Chandos-street, W.: at 5 P.M.

Cases and Specimens

Will be shown by Dr. Milligan, Mr. Cheatle, Mr. West, Dr. Dundas Grant, Dr. Dan McKenzie, Mr. Mollison, Mr. Sewell, and others.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Papers:

Dr. Alfred C. Jordan: Radiography in Intestinal Stasis (with lantern illustration).

Dr. C. J. Morton: X Ray Prognosis in Fractures (illustrated by lantern slides).

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Discussion on the Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System (introduced by Dr. F. W. M tt). The following have promised to take part:—Sir David Ferrier, Sir Victor Horsley, Dr. G. H. Savage, Dr. R. Russell, Dr. T. B. Hyslop, Major French, R.A.M.C., Dr. F. Buzzard, and Mr. A. Fleming.

ROYAL METEOROLOGICAL SOCIETY, Institute of Civil Engineers, Great George-street, Westminster, S.W.

THURSDAY (16th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (18th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Hunterian Lectures
ON
RECENT DEVELOPMENTS IN THE RECOGNITION, TREATMENT, AND PROPHYLAXIS OF SYPHILIS.

Delivered before the Royal College of Surgeons of England on Nov. 7th and 10th, 1911,

BY H. C. FRENCH, M.R.C.S., L.R.C.P.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

LECTURE II.*

Delivered on Nov. 10th.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—In my first lecture I dealt with the diagnosis of syphilis, and in this it is proposed to deal with treatment.

ABORTIVE TREATMENT.

Persons conversant with early syphilis require to know two clinical facts if the spirochæta pallida is not definitely demonstrated—namely, Was induration present in the chancre? Were the adjacent lymphatic glands discretely enlarged? In untreated syphilis the number of cases where these two signs do not exist is very small; so that when they co-exist treatment is fully justified. Otherwise we should always wait for more definite evidence of the disease. The Wassermann reaction, unfortunately, does not help us much in the primary stage. The alleged abortive cure of syphilis in the primary stage by excising chancres, or treatment by new drugs, such as hectine and salvarsan, requires to be received with very considerable caution and closely examined. The so-called primary stage varies in different countries and with different observers. Results are not infrequently worked out on the relative frequency of syphilis occurring in a consecutive series of all venereal sores, but this is obviously fallacious. In the last 100 cases of untreated venereal sores occurring at Malta not 10 per cent. were syphilis. During two months two years ago the bulk of venereal sores were syphilis. Relative incidence is largely dependent on the value of control at the source.

A statement from the bacteriological side was recently made[1] that "during the past 15 months about 300 cases have been treated with salvarsan. ..... The number of cases in which the only clinical evidence of infection was the primary sore is 22. ..... In none of the 22 cases has any symptom appeared since the treatment." It is further stated by the same writer that "treatment should be begun as soon as possible where there is the suggestion of a primary syphilitic lesion: even if spirochætæ cannot be found and the serum reaction is negative, treatment should be begun without delay." I merely mention this example, as such premature claims to abort syphilis are of not infrequent occurrence. To pursue such a policy on insufficient evidence does not further the best interests of accurate diagnosis, and the confidence of the patient may be destroyed.

ARSENICAL COMPOUNDS.

Dr. Hallopeau (France), using hectine (benzol-sulphone-para-amino-phenol arsenate of sodium) (containing 21 per cent. of arsenic) recently claims to have aborted syphilis in five out of six cases when the drug was locally used in the sheath of the penis in combination with mercurial and potassium iodide treatment. He states "that the time has arrived to treat syphilis by 30 daily injections of hectine," and he does not hesitate under these conditions to "allow marriage immediately to syphilitics who have followed this cure." By the courtesy of the French colonial authorities at Tunis a supply of hectine was recently sent to Malta for my use. Owing, however, to careful diagnosis on the lines previously mentioned, to the continued use of mercury, and to local preventive measures, early syphilis, as will be later explained, has been entirely stamped out in Malta this year, and in a garrison of 7000 troops there was no primary syphilitic case to try the new remedy on. Dr. Hallopeau also recently states "that iodide of potassium, in opposition to the generally received opinion, exerts a well-marked effect on the chancre."

Without claiming any originality in the matter, this marked effect on the chancre and lymphatic glands was pointed out in this country, and also in Italy 14 years ago,[2] and again 8 years ago;[3] but, like inorganic or organic arsenic in average cases of early syphilis, I do not at this stage pin my faith on potassium iodide as on mercury as a real curative agent, although it is potent in the removal of induration. Iodide of potassium, like salvarsan, is a good cicatrising agent, and has a powerful action on tissue metabolism, and is therefore capable of promoting the absorption of granulation tissue before its conversion into unalterable fibroid tissue. This would *ipso facto* allow local applications and bactericidal agents normally present in blood to have freer access to the spirochætæ. Mercurial inunction applied nightly to large indurations can effect a similar result and expedite local resolution. This local treatment and reduction of induration in the chancre is very important, and without doubt minimises the occurrence of relapsed chancres. It assists other medication to attack the spirochætæ embedded in fibrous tissue, and if "granule shedding" can "naturally" occur in spirochætæ local recrudescences of the chancre are thus explicable when treatment, local and constitutional, is not sufficiently intensive. It is necessary, however, to distinguish between aborting and modifying syphilis. Sir Jonathan Hutchinson has repeatedly pointed out that mercury administered in the primary stage in the manner recommended by him can effectually modify syphilis in many but not in all cases. He writes: "I never expect to see secondary symptoms now if I have seen the case before we begin."[4] It is common knowledge that if we push mercury in the first three months from contagion the patient declines in many instances to believe he has had syphilis because the secondary symptoms are so modified.

SALVARSAN.

Dr. Levy-Bing, whose work I saw in Paris a month ago, and who has given over 500 injections of salvarsan intramuscularly and intravenously, informs me that in the numerous cases in which he has tried it salvarsan does not ever abort syphilis even when given in four weekly doses of 0·6 gramme in the primary stage. Further, that nervous affections and severe relapse are very common six to seven months later, unless mercury is also prescribed. He mentioned two recent cases where meningitis, facial paralysis, and extensive skin eruptions had shortly appeared from his omitting to follow up the salvarsan with mercury. Dr. Levy-Bing speaks not only from the clinical but from the pathological point of view. He uses the ultra-microscope and performs a Wassermann test every two months. He finds that salvarsan in some instances produces a negative Wassermann test more quickly than mercury, but that it rapidly becomes positive again.

Mr. McDonagh states that he has "had 3 cases within the last 12 months of men early in the secondary stage cured by salvarsan return with a diffuse macular rash ..... which appeared a few weeks after the patient noticed the site of his original sore swell and become red." He considers that this certainly speaks for the efficacy of salvarsan, and states that "within the short time it has been in use already 7 cases of an undoubted re-infection have been reported." In the army such cases have not been regarded as cures or as re-infections, but are usually marked "relapse" in the syphilis register and sent into hospital for more intense and thorough treatment. Without in any way wishing to detract from the undoubted value of salvarsan in certain phases of syphilis, it is noticeable that in early syphilis, after using soamin and arsacetin, a similar condition of affairs occurred. There was marked temporary improvement and a gain in weight, but permanent benefit did not accrue, and relapses were early and severe. It is only three years ago that we were informed that[5] "Injections of soamin can be looked on as prophylactic in the majority of cases against any further development of the disease if given early and in sufficient quantities." On the evidence of cases treated at Woolwich I disputed this view at the time.[6] Eighteen months later, in March, 1910, an expert medical committee at the War Office stated as a result of impartial evidence collected from six large stations, "that the utility of these preparations (arylarsenates) as a prophylactic against syphilis has not been proved, and does not recommend their administration for that purpose."

There is abundant evidence to show that, like the arylarsenates, the claim of salvarsan to abort syphilis has not been substantiated. Applied locally it acts like a caustic

* Lecture I. was published in THE LANCET of Nov. 11th, 1911, p. 1315.

and expedites healing of the chancre in early syphilis, but other forms of local treatment have also this effect.[6] It is useful to inject salvarsan early to expedite the healing of primary lesions, especially amongst prostitute women, and rapidly follow this up with our *pièce de résistance*—mercury—as the real curative agent.

LOCAL TREATMENT.

Metchnikoff claims to have successfully inoculated the treponema pallidum and prevented syphilis by the early application within 24 hours from contagion of an ointment of calomel 10 parts and lanoline 20 parts. The use of soap or vaseline prior to coitus and washing with any antiseptic lotions immediately afterwards are also of great prophylactic value, and have been long recognised. Any oily substance would tend to block the minute orifices by which the micro-organisms gain an entry, and also tend to lessen the risk of abrasions caused by coitus. Cauterisation rapidly converts an unhealthy sore into a healing ulcer, stops phagedæna, tends to limit bubo formation, and expedites recovery. The application of a caustic does not in reality alter the nature of an infecting sore, and the condition of the adjacent lymphatics nearly always comes to our rescue. Further, a rash occurs in syphilis, whether the chancre is cauterised or not. I consider that non-infecting sores (soft chancres), if unhealthy-looking or discharging, should be touched with pure carbolic acid, which is comparatively painless, on admission and every third day, according to the indication of the particular case. Chancres, unless phagedænic, need not be touched if indurated and not ulcerated, or if they bleed profusely before and after touching, since such bleeding, as in simple inflammation, is a sign of commencing resolution. Many writers have advised the withholding of mercury in cases of phagedæna. I admit that caution and judgment are necessary. Local treatment by nitric in preference to carbolic acid, free exposure, prolonged baths, diet, and stimulants ordinarily suffice for phagedænic ulcers, except when the nearest glands are typical of syphilis, when mercurial inunctions should be used. A lowering treatment would have an unquestionably bad effect, whether dietetic or medicinal, especially if mercury is given when syphilis is non-existent.

MERCURIAL TREATMENT.

During the past 18 years my work has been almost exclusively confined to treating venereal diseases in large military stations at home and abroad. During this period I have extensively tried most of the recognised modes of mercurial administration, by the mouth, by inunctions, by injections, and by calomel vapour baths.

In the army, in the case of in-patients who are necessarily in hospital in the chancre and rash stage, we are chiefly concerned in trying to arrive at what best holds the syphilis in check. In the garrison of Woolwich in the year 1904 intramuscular injections of insoluble grey oil were ordinarily used for in-patients, and the inauguration of the out-patient system throughout the army dated from January of that year. In 1904 there were 331 admissions for syphilis, the average number of men constantly daily sick in hospital throughout the year with syphilis being 56. In October, 1905, inunctions of ung. hydrarg. and baths were commenced for in-patients, weekly grey oil injections being reserved for out-patients. There was a steady decrease in syphilis. In 1908 there were 53 admissions for syphilis, the average number constantly sick in hospital being only six. The following table shows these facts at a glance for the years 1904–1908:—

TABLE I.—*Syphilis: In-patients. Woolwich.*

Year.	Average daily strength of garrison.	Admissions: actual number.	"Constantly sick": actual number.	Ratio per 1000.	
				Admissions.	Constantly sick.
1904	5311	331	56	62·32	10·70
1905	4966	202	30	41·49	6·14
1906	5096	129	14	15·12	2·72
1907	4702	87	13	18·50	2·71
1908	5666	53	6	8·75	1·28

In 1904 grey oil intramuscular mercurial injections for in-patients and out-patients. In 1905–08 mercurial inunctions for in-patients—injections for out-patients.

I now come to the question of relapse. In Malta, in December, 1909, in a garrison of 6300 soldiers there were 171 cases remaining on the syphilis register under treatment by mercury, first as in-patients and later as out-patients, for syphilis, and out of these 31 suffered from relapse during the year 1909. In December, 1910, in a garrison of 6800 soldiers, there were 160 cases of syphilis remaining under mercurial treatment, with 21 relapses during the year 1910. These figures for relapse cases for the years 1909–1910 at Malta included men developing tertiary or other late manifestations of syphilis 5 to 10 years after contracting the disease. These figures embraced numerous transfers from other stations, foreign and home. Some of them were severe cases in men suffering from malaria, or the effects of tropical stations. Relapses were very unusual early in the disease. Syphilis cases in Malta, as at Woolwich, are ordinarily treated by inunctions of mercury in hospital in the primary and early secondary stage, and later, for military convenience, by injections of grey oil for out-patients. In 1911 the results are still better, and in a garrison of 7000 troops there is only one case of syphilis at present in hospital (a recent arrival with a severe throat relapse under salvarsan). There are 160 syphilis cases on the register doing their full duty free from any external manifestation of the disease. These figures compare favourably with those of any garrison in the world, and are a lasting tribute to the judicious use of mercury. Time prevents my dealing more fully with the clinical aspects of the relative merits of various modes of administration of mercury. They have received a great deal of attention lately.[7]

EFFECTS OF TREATMENT ON THE WASSERMANN REACTION.

To turn to the pathological aspect. We were asked to accept the Wassermann test as the real arbiter of the value of the various methods of administration of mercury and salvarsan. We will see, therefore, what recent reports tell us on these important points.

Mr. H. W. Bayly, pathologist London Lock Hospital, states that "82 per cent. of cases treated by inunction and 35 per cent. of cases treated by injection showed some effect of treatment after only three months." As far as he has gone, therefore, his conclusion is that inunction is the best form of administration of mercury, and he further gathers that Mr. McDonagh's large continental experience leads him also to this opinion. "Calomel injection seems much better than pill treatment, but not so good as inunction, as estimated by the Wassermann reaction. Potassium iodide and the arylarsenates have no effect on the Wassermann reaction, as far as three months' treatment is concerned." Neisser finds that iodide of potassium has an action on the Wassermann reaction.

At a meeting of the British Medical Association in 1910 Mr. McDonagh (London Lock Hospital) stated that "a patient should, before the disease has become generalised, receive the most active and vigorous form of treatment possible. Mercury, in the form of inunctions, is more potent in this respect than when given in any other form." Working at the Wassermann reaction on the continent he found that it was "almost a rule to obtain a 'negative' reaction after a patient had had a course of inunctions, or less frequently injections." As this bacteriologist has applied the Wassermann test in over 5000 cases his words carry very great weight, and he speaks from the clinical as well as from the pathological point of view.

Taking the Wassermann reaction as our test, Table II. indicates the ultimate effect on syphilis after a year, as distinguished from the immediate effect. Mercurial insoluble injections are contrasted with salvarsan injections on the Wassermann original reaction. The figures are some of those published by Major L. W. Harrison, who has probably done more research work on these points than any one else in this country.[8]

Judging from this table it would seem that after a period of about one year from contagion mercurial insoluble injection appears to be as efficacious as salvarsan as judged by Wassermann's original test, which is considered to be the standard. The course of mercurial injections employed, however, was extremely mild, and is recently obsolete in the army. A more intensive early course was introduced two years ago, and this may be productive of better results in future. Major Harrison states that "possibly injections may not be the best form in which to administer mercury." If so, it would appear wiser to test other mercurial methods before

TABLE II.

Tested after—	Results obtained by Wassermann's original test.		
	Total cases.	Positive.	Negative.
End of third course of mercurial injections (11th month). 14 injections in all given...	79	42	37
End of fourth course of mercurial injections (15th month). 18 injections in all given...	101	32	69
Three to 11 months after the last injection of salvarsan...	99	33	66

discarding them. Inunctions thoroughly applied in early syphilis appear to have a much greater effect on the Wassermann reaction.

Amongst a further series of 129 cases tabulated at the same time, in which salvarsan was used when mercury is reported to have failed,[9] it is observed that mercurial inunctions were only used in 8 instances, and merely as part of a mixed treatment in which inunctions took a minor share. There were 35 tertiary, malignant, parasyphilitic, or brain syphilis cases. These were unusually severe cases selected from other stations or those in which certain methods other than inunction had failed.

It is interesting to note in this connexion that Professor Fournier's valuable statistics on tabes in 1891 were based on "mercurial" methods other than injection.[10] He gives the statistics of 321 cases of tabes thus: 15 cases, no treatment; 8, potassium iodide, no mercury; 285 were treated by mercury, or more often a combination of mercury and iodide. Of these 285 cases, 70 were treated from a few days to two months, 108 from three to six months, 51 from seven to 12 months, 23 about 12 months, 20 from one to two years, 5 from two to three years, 6 for three years, and 2 for four years.

Sir David Ferrier says that "these statistics favour the view that a still more thorough and effective treatment might prevent the development of tabes altogether. ..... As regards salvarsan we had better 'wait and see.'"

Salvarsan was only placed on the market in December, 1910, and has not been issued for use to troops at Malta, so I am obliged to quote from the experiences of others. Major Harrison, in London, who received a free issue in July, 1910, had 18 clinical relapses amongst 115 cases of syphilis. In 31 instances the Wassermann test became negative after the use of salvarsan, but returned to positive. This occurred within a period of 3 to 11 months. Cases were selected for salvarsan treatment which had at least one year to serve. The results, therefore, on clinical grounds, if we accept relapses as our test, are apparently no better than with mercury.

Dr. Karl Lange[11] summarises the results of Wassermann reaction after salvarsan treatment in 268 cases of syphilis representing more than 2000 determinations at the Rudolf Virchow Infirmary. Eighteen cases, including one case of malignant syphilis and one of tabes, were negative before treatment. Nine cases were also negative where mercury had been used previously to salvarsan, and remained negative after salvarsan. Two cases of primary sore injected during exhibition of negative Wassermann also remained negative. Five cases of tertiary syphilis became positive after injection, and one died with a positive reaction. Ninety-seven cases remained positive after the salvarsan injection, of which 54 were absolutely unaltered. Amongst these, two adults and six children died during the positive period, although in these cases the degree of reaction had been partially reduced before death. Thirty-four cases exhibited a distinct reduction in the positive reaction during a period of observation extending over five weeks, but did not become negative. One case of severe laryngeal syphilis exhibited a strongly positive reaction for six weeks in spite of repeated injections of salvarsan. Neisser found that in only 10 per cent. of cases treated by salvarsan a positive Wassermann was changed to negative, and he pointed out that "the reaction cannot decide whether the cure is permanent or not." He pleads for "a combined treatment with these injections and mercury or iodide of potassium," and recommends the use of mercury for three years. Professor Werther, who has treated some 350 cases with salvarsan, states that "in cases treated by him in October, 1910, only 12 per cent. gave a negative Wasserman. ..... The combination of mercury with salvarsan has a more rapid effect on the reaction than a second dose of salvarsan." Professor Ehrlich states that "in some cases a negative reaction may be present, but after an injection of '606' the reaction becomes positive." If this is so, one naturally asks what is the potential value of a Wassermann test in syphilis, as the figures of Dr. Karl Lange previously quoted, and those of numerous other independent observers, indicate that a large bulk of the cases remain positive, whereas with mercurial inunctions they have been proved to become negative. One assumes that to obtain a negative reaction is the object of the Wassermann test and our guide to the relative therapeutic value of the remedy. This is the usual criterion of all pathological reports when attempts are made to assert the superiority of salvarsan over mercury.

As regards mixed treatment by salvarsan and then mercury and iodide of potassium, a similar plea was put forward with atoxyl, soamin, and arsacetin; and atoxylate of mercury was later evolved by Uhlenhuth which has proved of very little use. Dr. G. Pernet refers to "therapeutic rockets which come down like sticks," and Mr. C. F. Marshall considers that "an attempt is made to break the fall of salvarsan by a parachute of mercury and iodides." If "606" is to become a substitute for mercury it must be judged on its own merits. An adjuvant is a different matter, and as such salvarsan, according to the literature, appears to have a definite place in selected cases, mainly in those in which iodide of potassium was formerly used. The almost universal trend of opinion now is that salvarsan is not to be considered a substitute for mercury in average cases of early syphilis. The effect of this drug on induration in the chancre and the induration in the lymphatic glands is reported by numerous observers to be slight and not nearly as marked as with mercury. Such induration and enlarged glands are the repositories of syphilis, and, if not thoroughly reduced, relapse is usually ensured. The therapeutic action of salvarsan may be brilliant, but the effect is temporary judging by clinical reports and the evidence of the Wassermann reaction. In parasyphilis salvarsan is of little avail, judging by published opinions. In certain ulcerative conditions, in malignant, laryngeal, and tertiary syphilis, salvarsan is valuable, also in mutilating syphilis where phagedæna attacks the lesions, or in persons suffering from mercurial poisoning resulting from injudicious administration.

COMPARATIVE TOXICITY OF ACTION.

In a recent review on the "Experimental Chemistry of the Spirilloses"[12] it is stated: "We have for a long time had in mercury a specific remedy for syphilis, but a great disadvantage consists in its intense toxicity in relation to curative action." Is this impeachment of mercury fair, is it true?

As regards relative toxicity of action, there are 35 recorded deaths under salvarsan quoted in English literature[13] in a period of a little over a year. Dr. Levy Bing informed me of two other deaths under salvarsan in Paris in the week preceding my arrival, and four deaths previously, none of which had as yet been published. They did not occur amongst persons *in extremis*, but, I gather, amongst otherwise healthy adults. He is of opinion that the total number of deaths under salvarsan probably amounts to 70 or 80 persons.

Intravenous mercurial injections were introduced in 1864 by Scarvenzio and gave rise to some toxic signs, including death, and for this reason were discontinued. In a recent book on salvarsan Mr. J. E. R. McDonagh states that under mercurial injections the deaths number 70. The cases, however, are not quoted or the references given; I can only trace 26 under intramuscular mercurial injections.[14] These deaths under mercury date from 1864 and occurred over a period of nearly 50 years in a much larger number of cases. The toxicity of salvarsan, therefore, would appear to be at least equal to, if not greater than, that of mercury, quite apart from other recorded toxic signs. In the British Pharmacopœia both are classed amongst the poisons.

The occurrence of cancer after the use of arsenic was recently brought forward by Sir Jonathan Hutchinson. This is at present *sub judice*. One drawing on the table from

the College Museum shows an extensive dermatitis and so-called psoriasis directly due to arsenic.

The question arises whether salvarsan, the most recent organic preparations like atoxyl, is decomposed in the system into inorganic arsenic. Dr. J. M. Fortescue-Brickdale (lecturer on pharmacology, Oxford) states: "In man the excretion of atoxyl usually amounted to 50 to 90 per cent. within nine hours, partly as atoxyl and partly in another form, the latter being found in the urine for several days. The atoxyl retained in the body is to some extent decomposed, so that after a sufficiently long time enough inorganic arsenic is formed to produce the ordinary toxic symptoms. When atoxyl is applied to the treatment of syphilis, chorea, or any of the grave forms of anæmia, there is no evidence that any further action takes place than can be ascribed to the gradual splitting off of inorganic arsenic, and thus no advantage is gained in giving a rapidly eliminated form in large doses rather than one which, being slowly excreted, can be given in small ones."

I have used in selected cases of syphilis Donovan's and Fowler's inorganic arsenical preparations by the mouth for 18 years with great success. Others testify to their value, and they have existed in the British Pharmacopœia for 50 years. They are apparently less toxic, as no death is known. They are most valuable in late secondary or tertiary manifestations, and in cases where malaria exists in association with syphilis. Sanatogen, which is organic phosphorus, is also valuable in severe and malignant syphilis, and causes a rapid gain of weight, when cases previously unbenefited by mercury or potassium iodide rapidly improve, and these drugs can then be given with advantage.

Mr. Ernest Lane has drawn attention to certain difficulties in the technique which occurred with intravenous mercurial injections. These, no doubt, can be obviated, but the veins may be friable in syphilis, and in one instance that I saw the entry was only made after 11 attempts on the veins of both arms by an experienced man.

Some Canons regarding Results of Treatment.

In forming an opinion on the relative value of different drugs in treating syphilis the following canons may prove useful: First, the drug must be tried alone and judged on its own merits. Secondly, the manifestations of early syphilis, more especially induration in the chancre, must be removed in four to six weeks, and glandular enlargements, when they exist, must be rapidly reduced in three months from contagion. Mercury can do this. Thirdly, the result of the Wassermann original reaction should be recorded at three, six, and nine months, if this test when the technique is standardised is later accepted as conclusive evidence of syphilis. Fourthly, the recurrence of symptoms or relapse within the first 6–12 months from contagion must be noted, bearing in mind that a large number of cases of syphilis are often very mild and may not relapse even with an entire absence of treatment until parasyphilis occurs. Fifthly, the later occurrence, or otherwise, of tertiary manifestations and parasyphilis recorded. Sixthly, the mortality.

Before discussing some general considerations I draw your attention to some drawings of yaws on the table. This is a disease closely simulating syphilis, but due to a different spirochæta. In connexion with remarks in my first lecture on the varieties of spirochætæ found in primary syphilitic chancres, it is possible that we may find different types of syphilis due to other spirochætæ, just as varieties of trypanosomes are found.

Observations on Treatment.

As far back as 1786 John Hunter condemned "the ungrateful and unsettled mind of man" in his endeavour to obtain a substitute for mercury in the treatment of syphilis. He wrote: "If there is such a thing as a specific, mercury is one for the venereal disease ..... yet mankind are in pursuit of other specifics for this, as if specifics were more common than disease."[15] If for the word venereal we substitute early syphilitic disease, then Hunter's words are as true to-day as at the date when they were written. In amplification of Hunter's words the following facts require consideration before we lightly dismiss mercury in favour of arsenic. The grave effects of syphilis are largely due to the original intensity of infection, to personal susceptibility to the action of the virus from lowered general health, to racial susceptibility, to intemperate habits, to the neglect of early treatment, and to the injudicious use of mercurial preparations. The primary and early secondary stages run a definite course, and no line of treatment can absolutely prevent the evolution of manifestations, but good treatment in hospital in the early stages markedly ameliorates the general blood condition.

Owing to our ignorance of the laws of assimilation and elimination, it is unwise to give the patient in any stage as much mercury as he can stand, because this practice, though advocated by some persons, constitutes an abuse of the drug. This may result in mercurial stomatitis, or mercurial stasis and poisoning, from at first being unduly accumulated and later too suddenly eliminated. This would also affect the general health, which is a most important consideration, as the manifestations of syphilis are usually in inverse ratio to it. Treatment should, I think, be directed towards enabling the patient to take the drug by regulating elimination, and inducing an increase of metabolism by baths, food, and general exercise in the fresh air. If the bactericidal properties in the blood are to effect the cure of syphilis, this must necessarily result from increased metabolism due to the careful administration of mercurial or other preparations. As a result of such administration the lymphatic glands become reduced in size, and so continue their depurative and eliminatory function. When this fails they break down and suppurate. This result is not infrequently seen in neglected or badly treated syphilis. Too long a continuance of a large dose in any form creates a markedly retrograde effect, and gives rise to anæmia, loss of weight and general condition, as well as acting as a systemic poison, and it probably prevents antibodies forming in the blood. The factor "general condition," when adequately maintained, has no doubt as powerful an effect as the mercury in improving the status of the red blood corpuscles, and in eliminating the syphilis by improving the tone of eliminating organs, such as the liver, kidneys, and skin. "If blood counts be made it will be found that the count of red cells and the amount of hæmoglobin increase during the first three weeks of mercurial treatment begun when secondary manifestations of syphilis have occurred. After that time if mercury is still given the hæmoglobin and, later, the number of red corpuscles begin to decline."[16] Hydrotherapeutics and electro-therapeutics are useful adjuncts to a mercurial course, and a valuable complement after it.

Before iodide of potassium is administered the question of renal sufficiency should be adequately gauged. If albumin is present or the quantity of urine is insufficient the iodide eruptions are likely to occur, and hence the value of free dilution of the drug together with hot-air or electric-light baths. These exercise a markedly beneficial effect on the kidneys and assist elimination by the skin. The headache and osteocopic pain of early syphilis may rapidly yield to potassium iodide alone or in combination with mercury, and a pustular syphilitic rash is markedly benefited. The drug may give rise to headache if albumin is present in the urine. Potassium iodide is more obviously beneficial the further the stage from primary infection, and its use, therefore, is imperative in the late secondary and tertiary stages or in any manifestations, however early, such as malignant syphilis presenting the attributes of those stages. This drug is most valuable in cases of early syphilitic orchitis, in periostitis, nodes, gummata, gummatous ulcerations, and in threatened brain or cord lesions. Patients who are intolerant of small doses, such as gr. v., may take a larger one with impunity. The drug is best borne about an hour after meals in dilute solution in such vehicles as water, milk, and sarsaparilla. The depressant action is best avoided by prescribing it for short periods of 10 to 14 days at a time, and in solution with ammonia carbonate, and by administering the large dose at bedtime and avoiding its use in the early morning. It is then not so likely to derange digestion or cause depression. A course of a month once a year is valuable as a precautionary measure against parasyphilitic affections, and is strongly advocated by Sir William Gowers. The drug, as a matter of routine, should always be given as the complement of the mercurial course, since it is generally believed to assist in the gradual elimination of the accumulated mercury, and so guard against mercurial stasis and poisoning. It should not be given when mercurial poisoning has actually occurred. It also acts, especially when combined with sarsaparilla, by relieving the liver and kidneys, which may be chronically congested or lardaceous. Potassium iodide can remove the barricades of nascent fibrous tissue in which the syphilitic virus or its toxin is no doubt lodged in latent and later stages, and thus permits the leucocytes to

enter and effect the removal of the virus or its products, and this explains the lessened anæmia of the patient in suitable cases. The drug often rapidly reduces the enlarged glands, and its moderate use, therefore, causes a more healthy tone of tissues, blood, lymphatics, and organs, which can then more naturally overcome the localised effects of the spirochæta. In certain stages of threatened brain syphilis which have been neglected in the early stage mercury may prove more valuable, but commonly in "syphilis grave" or in "malignant" syphilis mercury may prove quite useless, and general condition is the first consideration.

Quinine in dilute acid solution is often most valuable precedent to, or after, the first mercurial course in cachectic cases. Whether it exerts a specific action on the treponema pallidum as on the malarial parasite is uncertain, but I always temporarily substitute it for mercury if there is an associated malarial history or if syphilitic fever is present. As early syphilis is associated with a loss in numbers of the red blood corpuscles and in the amount of hæmoglobin in these cells, quite possibly its chief action may be in overcoming the degenerative action, and thus assisting the blood to deal with the inroads of the virus in the early and more remediable phases of the disease by an increase in its phagocytic power or by the formation of antibodies. Cod-liver oil and iron are similarly valuable for their hæmatinic powers. Any drug, however, or any means which tend to reduce the number of spirochætæ in the system in the early stages, will consequently lessen the amount of toxin produced which can later injure the central nervous system and give rise to parasyphilitic affections.

The very greatest advantage may accrue from a cessation of mercury or potassium iodide and the substitution of other tonic remedies. I think that this is more especially the case in alcoholic, scorbutic, anæmic, malarial, or tubercular subjects, and in malignant syphilis. There is no class of disease in which the beneficial results of judicious and early treatment are so marked as in syphilis. If the remedy used is doing good the result is early apparent and the manifestations of the disease disappear; if, on the contrary, the manifestations are stationary or growing progressively worse the remedy is inadequate and fresh methods should be essayed, either by an increase or decrease of dose or the substitution of other drugs and remedies. If there are ulcers in the throat or mouth local treatment is requisite, and a minced meat or stew diet is essential to successful results. Otherwise the patient tends to lose weight if he is unable to masticate or swallow too solid food, and mercury would only aggravate matters. Success more often depends on maintaining the strength by the judicious use of stimulants and nutritious food than on drugs. This is especially true in cases of iritis, severe throat lesions, necrosis of bone, and in malignant syphilis.

PROPHYLAXIS.

Coming to the important question of prophylaxis, there are two essentially different modes of State intervention. First, the system known as Regulation, which implies registration and attendance. The second mode is "to require doctors and others to notify all cases of actually existing disease in persons of whatever class or sex to the health authority, who inquires into the means of segregation and treatment (as in the case of other infectious diseases) and is empowered to remove the patient to hospital if necessary." In the case of poor persons this implies a certain outlay for hospital accommodation and food, but it pays the State a hundredfold. Notification is not unequal between men and women, nor does it unduly encourage immorality. Inquiries extending over 20 years in Brussels elicited the fact that amongst 1523 out of 3505 women the primary cause of prostitution is poverty. If, therefore, prostitution is mainly dependent on poverty, and it is impossible to remove the latter, prostitution must be supervised. The late Dr. Parkes said: "In the case of venereal diseases the State must as much protect its citizens as from the danger of foul water or the risks of any other perilous and unhealthy trade."

I have outlined elsewhere the prevalence and some of the fundamental facts on which the "control of venereal diseases at their sources in civil communities" is dependent.[17] It is merely desired to point out now that in India, where control has existed since 1897 under the Cantonment Act, venereal diseases have steadily decreased year by year in the 70,000 British troops always stationed there amongst a native population of 300 millions. In 1895 in India the admissions to hospital for all forms of venereal disease reached the enormous total of 537 per 1000 of strength. In 1908 the admission-rate was only 70 per 1000, and yearly less since. In 1897 there were 661 invalids from India to England for venereal disease, and in 1908 only 59 invalids.[18] In 1895 there were over 3000 soldiers (three regiments) constantly sick in hospital with venereal diseases; and in 1908 only 500. This is an enormous saving in men and money, as a trained soldier landed in India costs the State £100. Coming to the civil aspect in England, A Royal Commission on the Blind, the Deaf, and the Dumb, which reported to both Houses of Parliament in the year 1889, estimated that about 7000 persons in the United Kingdom had lost their sight from ophthalmia neonatorum, and assessed the cost to the State for these cases of preventable blindness at £350,000 a year. This disease is recently notifiable. Syphilis is directly responsible for about 12 per cent. of all male admissions to lunatic asylums. This is independent of the cost of maintaining cases in workhouses and infirmaries.

When quite a young man I expressed the view that it was quite feasible to stamp out syphilis if the necessary measures were taken.[19] The ideal of my youth has borne fruit in my old age. At Malta freshly contracted syphilis has been practically stamped out during this year, and recently soft chancres very nearly so. In the year 1911 to date there have been only three or four cases of freshly contracted syphilis amongst troops at Malta. In 1909 there were 87, and in 1910 35 freshly contracted cases. There is only one "venereal sore" case at present in hospital. The troops number 7000. An equal number of sailors of the Royal Navy arrive periodically, and the population of the island is a quarter of a million persons. It is not proposed to weary you with statistics, but merely to mention how this has been done: (1) Confidential notification applied to both sexes; (2) segregation of diseased men and women in hospital in the early contagious period of disease for a few weeks; and (3) prophylaxis by efficient in-patient and later out-patient treatment.

You will say, "Ah! but the clandestine—how do you control her? It is she, and not the professional prostitute, who spreads syphilis five times out of six." This may be so in large cities, and it is very difficult to control, but this is an insufficient reason for doing nothing. No one asks for the Contagious Disease Acts to be reapplied to 12 towns in England, but common sense in dealing with these matters would appear to suggest that some form of public health control should be exercised in all towns, since the disease in question is worse than small-pox. The following are very practical suggestions:—

1. Rigid suppression of solicitation in the streets by women, or by men, who act as middlemen and finance the situation, or live on the earnings of women. Police action is possible under the Town Clauses Act of 1847. The Act is applied in London, and the police have power to arrest persons soliciting without the person solicited being called on to give evidence.

2. The prostitution of girls under age should be suppressed. At the St. Lazare Hospital, Paris, minors are separated from the elder women in the wards and in the chapel.

3. Complete and compulsory courses of instruction in venereal diseases should be instituted in every university so as to ensure the training of really competent practitioners.

The foregoing were among the main recommendations of an International Conference in Brussels in 1899.

In conclusion, the St. Lazare Hospital, Paris, built in 1683, first convent, then prison, now part hospital, part prison, has 1000 beds for the lower classes of diseased prostitutes. There is a life-size, gruesome picture over the chapel entrance of a dead prostitute being carried out in solemn state for burial. The picture, no doubt, is placed there to remind those who enter that "The wages of sin is death." The Scriptural reading, however, appears more humane, "Let him who is without sin cast the first stone."

Clinical Lecture
ON
COLOTOMY
AND
SOME MISCONCEPTIONS OF ITS RESULTS.

Delivered at Charing Cross Hospital

BY PETER DANIEL, F.R.C.S. ENG.,

SURGEON TO METROPOLITAN HOSPITAL AND TO GORDON HOSPITAL FOR RECTAL DISEASES; ASSISTANT SURGEON TO CHARING CROSS HOSPITAL.

GENTLEMEN,—There are few operative measures that engender in the mind of patients, nurses, and practitioners so much dislike as colotomy. The reason for this is not difficult to understand; yet this is eminently a life-saving and pain-saving procedure, and its evil repute is, I am quite convinced, not justified. I would go further and say that the discomforts and disadvantages of colotomy are unduly magnified. Indeed, evils which are in no way due to the artificial anus but depend upon other factors are laid to its account, and it is the sifting of these quite extraneous evils from those inherent to the colotomy itself, and the placing of them where they rightly belong, which is my purpose to-day.

I do this because I know that the fear or dislike of colotomy leads to a great deal of unnecessarily prolonged suffering, and even to painful and torturing deaths, for no one can deny the agony of a death by intestinal obstruction. I would say, boldly and without hesitation, that many of the defects or disadvantages attributed to colotomy are so attributed from erroneous conceptions of their origin, and from ignorance of the nature of the function of the sigmoid and rectum.

Even such an apparently old subject as the anatomy of the sigmoid and rectum, as taught even now in quite "up-to-date" books, is wrong, in view of recent research by modern methods and advantages—I mean the gross anatomy; while the character of the vermicular action of the large bowel has hitherto been quite misunderstood, and upon this misconception I must strongly insist, because the normal expulsive movements of the large bowel are so exceedingly sluggish that they could not possibly give rise to diarrhœa even in the absence of a sphincter: diarrhœa means abnormal stimulation of the peristalsis, and not loss of sphincter control.

SUPPOSED DISABILITIES ARISING FROM THE OPERATION.

Let us first see what the supposed disabilities consequent on colotomy are:

1. Loss of the sense of desire to defæcate—i.e., warning.
2. Excessive number of actions—i.e., diarrhœa.
3. Loss of control over defæcation.
4. Excoriation of the skin.
5. The wearing of an apparatus.
6. The presence of an artificial anus on the abdomen.

The latter two are inevitable, but in practice they are really the minor of the evils, and if the former disabilities are reduced to a minimum the wearing of an apparatus is a small penalty to pay for relief from pain and the peaceful prolongation of a life—a life which may be valuable and useful.

To come to actual facts, therefore, we find that it is the inability to know when the bowel is going to act and how often it is going to act per diem which are the two great practical factors, because the amount of skin excoriation is largely dependent upon these conditions.

SENSE OF WARNING.

Now everyone attributes the loss of warning to the fact that in colotomy the bowel is opened above the sphincters ani. This is entirely erroneous. The sense of warning in no degree depends upon the sphincters ani, but chiefly upon the relaxation of the lower sigmoid sphincter, which exists where the pelvic colon (sigmoid) joins the rectum. The relaxation of this coincides with the passage of the fæcal mass from the sigmoid into the rectum.

It must be remembered that the rectum is normally quite empty. Certainly the lower half (ampulla) is accepted by all authorities as being empty, normally, and that the lower part of the pelvic colon or sigmoid is the fæcal reservoir, where the normally inspissated content of the large bowel rests until it is expelled, which in normal persons is every 24 hours.

In so far as the warning preceding defæcation is concerned, therefore, its loss depends, not upon the absence of the rectal sphincters, but of the loss of the sigmoid sphincter. However, there is evidence to show that sensory stimuli must precede the relaxation of the sigmoid sphincter—analogy alone would suggest this; and that these sensory stimuli originate, not only from the mucosa covering the sphincter of the sigmoid, but from a large extent of the sigmoid mucosa; hence the loss of the sigmoid sphincter with its mucosal covering does not remove all the sources whence the premonitory sensory stimuli preceding defæcation arise.

Clinical evidence, derived from the sensations of patients who have colotomies, clearly shows that most of the successful cases have very definite warning of the impending action of their colotomies; while others learn by certain sensations peculiar to each, and which are not normal warnings, when their bowel is going to act. Hence, even though the acutest warning of the impending action of the bowel is superseded by the performance of a colotomy, all warning is not cut off, or if it is "auræ" develop which efficiently replace the warning. Consequently, we cannot maintain that one of the great disabilities of colotomy is the inability to know when the bowel is going to act.

HOW OFTEN IS THE COLOTOMY GOING TO ACT (DIARRHŒA)?

This is the great difficulty with colotomy, and it is usually entirely attributed to the loss of the sphincters ani.

Cause of Diarrhœa.

First, consider what this means. In effect this explanation of diarrhœa in colotomy says the fæces run away from the bowel because the colostomy opening has not a sphincter, like the normal anus, wherewith to restrain the fæces. This is an entirely wrong explanation. The chief reason the patient has diarrhœa, or even why he has more than one action, or at most two actions, of the bowel per diem, is that the mucosa of his colon is chronically inflamed—i.e., the patient has always some degree of colitis. The best proof of this assertion is the result of treatment. Cure the colitis or remove its cause and the diarrhœa ceases, yet is the patient still minus a sphincter. So it was not the absence of the sphincter which formerly permitted the diarrhœa.

Is this assertion reasonable? You have only to follow the reasoning to its logical conclusion to see that it is so. In the person whose sphincteric apparatus is intact—sigmoid and anus—the presence of colitis in a late stage will result in diarrhœa, and sphincteric action is absolutely incompetent to prevent it—i.e., the diarrhœa occurs in spite of the presence of normal sphincters.

Understand clearly what I mean. A normal person empties the sigmoid once daily. The fæcal mass lies in the sigmoid stationary, not because it is retained there by a sphincter, most certainly not by the anal sphincters or the levator ani, but because the *vis a tergo*—i.e., the propulsion forwards of the contents of the transverse and descending colon—is very slow and gradual, so that until a sufficient mass of fæces has had time to accumulate in the sigmoid the peristaltic action of the latter remains in abeyance. Hence, for example, the presence in the sigmoid of the débris of the preceding day's breakfast alone is insufficient to excite the peristalsis of the sigmoid, and it is not until the débris of the preceding evening meal has arrived in the sigmoid that the total bulk is sufficient to start peristalsis.

The best stimulant to bowel action is distension. When the débris of 24 hours food has collected in the sigmoid the distension it produces suffices to start the process of defæcation, the sigmoid sphincter relaxes, peristaltic action is excited, and the fæcal mass is driven into the rectum, when the desire to empty the bowel becomes imperative and voluntary action is called into play, either to expel the mass or to retain it. This voluntary retention is partly exerted through the sphincters ani and the levator ani.

What happens, however, if the mucosa is inflamed or the muscular coats unduly excited? The débris of each meal as it arrives at the sigmoid is *not* retained at all or only for a short time, but on the contrary is hurried into the rectum and expelled—in short, diarrhœa results, and in spite of normal sphincters. In fact, we find that the sphincters are chiefly expulsive agencies, being essential for the cleanly completion of defæcation.

Apply this reasoning to the patient's case when he has a colotomy. If the surface of the colon is healthy—i.e., free from colitis—the débris of the food will gradually collect and remain in the sigmoid until sufficient bulk has accumulated to excite the normal peristaltic action, when an evacuation occurs. This bulk of stool usually represents in the normal patient the food débris of the preceding 24 hours; hence a second action should not be necessary, or possible even, for another 24 hours.

On the contrary, if the mucosa is catarrhal, the undue stimulation excited partly by the excess of mucus, partly by the excess of flatus which is almost always associated with catarrh, and by the muscular stimulation produced by the toxins present, all these stimuli result in excessive peristaltic activity of the bowel wall; hence inability of the sigmoid to retain the débris of more than one meal (or even less than one meal) which is expelled from the bowel as soon as it arrives instead of lying in the sigmoid until the débris of the 24 hours has collected, when a normal stood would result. So we see that diarrhœa in colotomy is not due to the absence of a sphincter. It would, indeed, be a mighty sphincter which could for long retain the stool in the presence of catarrh—i.e., colitis. That the colotomy is unjustly blamed as the cause of diarrhœa is therefore patent.

Condition of Bowel in Colotomy Patients.

We generally find that colotomy is performed in a bowel already the seat of colitis, either above a malignant growth or a stricture, or infective ulceration of the rectum; often the two latter conditions are part of a process diffused throughout the bowel, and one often most intractable to treatment, and a colotomy may or may not be proper treatment.

Above a cancerous growth the bowel is always catarrhal, and for some time after the performance of a colotomy some degree of diarrhœa will result in these cases, until, indeed, the catarrhal condition subsides as a result of the relief of the chronic intestinal obstruction. When this is attained the bowel will act once, or at most twice, daily. If, however, the catarrhal condition of the bowel is maintained by any cause then the diarrhœa persists, and will persist, till the cause of the catarrh is removed, and for a short time longer.

Oral Sepsis.

The obstruction, and hence the catarrh, produced solely by the growth being relieved by the colotomy, is there usually a cessation of the diarrhœa? I regret to say No, because in most cases there is an additional source of catarrh present. It is to this *additional* cause of catarrh or colitis that most of the inconvenience or evil attributed to the colotomy must be charged; certainly not to the absence of a sphincter. What is the commonest cause of this "residual" colitis? In my opinion it is by far most often due to oral sepsis. So with a not inconsiderable experience of colotomy, I wish to emphasise strongly the proposition *that the comfort of a patient with a colotomy is directly proportionate to the presence or absence of oral or nasal accessory sinus sepsis.*

Site of Colotomy.

Granted, therefore, that this corollary is correct, it follows that the many ingenious methods of endeavouring to manufacture a sphincter "to prevent diarrhœa" are not only unnecessary but are bound to fail to effect this object—not even nature's sphincters can prevent diarrhœa. But inasmuch as it is impossible by any method of performing colotomy known to me to retain the whole of the fæcal reservoir, the sigmoid, the operation, by reducing the storage capacity of the bowel, inevitably interferes to some extent with the normal capacity to hold the accumulation of the 24 hours' food débris, which means that the one normal daily evacuation will be interfered with. The nearer the rectum the colotomy opening is placed the less do we reduce the storage capacity, and *vice versâ*. Hence the selection of the transverse colon as the site of a colotomy is absolutely indefensible, while the historical method of selecting the proximal end of the sigmoid is also incorrect; the question of prolapse apart, the ideal site for a colotomy is the junction of sigmoid and rectum.

Regulation of Diet.

It is because we do reduce the storage capacity of the colon that throughout I have reiterated that a successful colotomy, even in the favourable cases—namely, those free from oral sepsis—may act twice daily. This, however, depends largely upon the quantity and débris-producing qualities of the food partaken, and is to this extent under the patient's control.

If we have so reduced the capacity of the sigmoid that instead of being able to hold the débris of all the four meals taken daily it is only able to retain that of three meals, it necessarily follows that when this amount of débris collects it is evacuated as a stool, while the débris of the last meal of one day is added to that of the following day, and so on. Irregularity of the bowel must result; but if the nature of the food can be so adapted that the amount of débris produced per diem is so reduced as to enable the diminished sigmoid to hold the débris of all four meals, then the one daily evacuation of the bowel is not interfered with.

CONCLUSIONS IN FAVOUR OF COLOTOMY.

We thus see that—

(1) There is ample warning of an impending stool;

(2) If there is no oral or accessory sinus sepsis there is no diarrhœa;

(3) While regulating the diet permits of control of defæcation;

(4) Skin excoriation is very greatly reduced, but as this is also dependent upon the mucus exuded from the exposed mucosa it is not entirely done away with.

REMOVAL OF SOURCES OF PUS.

Before doing a colotomy, therefore, all sources of pus likely to be swallowed must be thoroughly dealt with, and I mean thoroughly, not in the half-hearted manner so often adopted, and inevitably bound to result in disappointment. This will prove the most important of the accessory steps to the operation of colotomy, and should be carried out as soon as it is decided a colotomy is to be done, and must not be left until the time the colotomy is done, unless of course the latter is performed urgently, when, if possible, the mouth or nose should also be attended to—i.e., at the same time.

SOME POINTS IN THE OPERATION.

As regards the actual operation there are two chief points to be considered: (1) That the whole of the fæces must be passed through the colotomy, hence the spur must be effective; (2) that prolapse of the bowel in the future must not take place.

Effectiveness of Spur.

In order to be certain that the spur is effective in the operation usually performed, the mesenteric border of the sigmoid must be at or near the level of the skin. It consequently follows that the whole diameter of the gut lies above the skin, and the surest way of ensuring this is to pass a glass rod though the mesentery to sustain the bowel. This is the most effective way of making a spur; it is also much less painful than any form of stitch (the through-and-through suture is really painful) and it is the least septic also. The glass rod is 4½ in. long, ¼ in. in diameter, and over the two ends are passed ¾ in. to 1 in. of rubber tubing to prevent its accidentally slipping out of the mesentery. One of the rubber sleeves is slipped off when the glass rod is finally removed on the seventh to tenth day.

Prolapse.

With regard to future prolapse, it has always been taught that the way to prevent the proximal part of the colon from intussuscepting through the colotomy opening is to pull down the colon until it is "taut"—i.e., until there is no slack part of colon between the place where the colotomy opening is to be made in the bowel and the descending colon where it is bound down to the left kidney. This advice is quite correct, but unfortunately the method removes almost all the sigmoid reservoir and interferes with the desirable state of one daily action of the bowel.

The best method of performing colotomy, therefore, is not so easy to decide; and when it is to be a permanent thing, as in cancer of the rectum, it is still further complicated by the method now in vogue of attempting the removal of "all the lymphatic watershed, including a great deal of the sigmoid

and most of the meso-sigmoid," a proceeding which, in my opinion, neither the anatomy of the part nor clinical evidence justifies.

With regard to prolapse, it is my experience that the constant expulsive effort due to diarrhœa is the most important predisposing factor to this painful and disagreeable complication. Another is the "drawing" effect of even the best made colotomy receptacles, due, I think, chiefly to the want of an air vent, the introduction of which tends to leaking. The more the sigmoid retains its normal function of a reservoir the less the probability of prolapse, and, as I have indicated, we can prevent diarrhœa, hence we can practically remove the most important factor conducing to prolapse.

Prevention of Possible Nipping of Intestine.

In conclusion, I would like to warn you that in performing the operation of colotomy by the so-called "gridiron" method—i.e., the separation of the flat abdominal muscles in the direction of their fibres as we do in appendicectomy—it is wise after making the incision in the tendinous part of the external oblique in the direction of its fibres to notch the aponeurosis at right angles to the fibres, as I have known at least two deaths follow the operation of colotomy, from nipping of the wall of the intestine by the strong tendinous edge of the external oblique of such a severe degree as to lead to a linear band of necrosis of the bowel wall—i.e., there was no effective obstruction to the contents of the bowel, which could be and were expelled by mild laxatives or by passing a tube into the bowel, but death was due to the intense toxæmia which we now know is associated with even a linear necrosis of the bowel wall and the virtual obstruction which is produced, but which in a colotomy one could mechanically overcome. To all intents and purposes strangulation by a band occurs.

THE DIFFERENTIAL DIAGNOSIS OF SYPHILIS AND PARASYPHILIS OF THE NERVOUS SYSTEM.[1]

BY F. W. MOTT, M.D. LOND., F.R.S., F.R.C.P. LOND.,
DIRECTOR OF THE PATHOLOGICAL LABORATORY OF THE LONDON COUNTY ASYLUMS; PHYSICIAN TO CHARING CROSS HOSPITAL.

FOURNIER was the first to express the opinion that tabes dorsalis is a post-syphilitic disease, and Erb in Germany and Gowers in this country have done more than any other neurologists to support this doctrine of Fournier. Esmarch and Jessen, and later Kjelberg, were the first to call attention to the fact that general paralysis occurred especially in persons who had suffered with syphilis, but it was Fournier who really put forward the doctrine that general paralysis was, like tabes, a consequence of syphilis, and that the two diseases were so similar in their etiology that they might probably be regarded as one disease affecting different parts of the nervous system. The inoculation of a number of general paralytics with no history or signs of syphilis with the virus of a hard chancre without any signs of infection resulting led Krafft-Ebing to postulate the dictum "general paralysis is the product of syphilisation and civilisation."

When I was appointed pathologist to the London County Asylums I found no mention of syphilis as a cause of this disease and comparatively little of other mental conditions in the annual reports. This struck me forcibly, for as a neurologist I had been greatly impressed in my hospital experience with the fact that of all the causes of organic disease of the nervous system syphilis easily occupied the first place. I found that careful inquiry in cases of general paralysis revealed the fact of antecedent syphilis much more than had been suspected; still, the obvious syphilitic residua of scars of gummata and other tertiary manifestations in the body were relatively infrequent. I found that cases of syphilitic brain disease with dementia were called general paralysis, also cases of Korsakoff alcoholic psychosis; but etiologically and pathologically, especially in the light of recent research, these are quite different diseases and can usually be differentiated clinically.

[1] A paper read before the Medical Society of London on Nov. 13th, 1911.

A number of causes were asserted to be the agencies capable of inducing general paralysis, and while not denying that alcoholism, sexual excesses, inherited neuropathic and psychopathic predisposition, worry and excessive mental strain—in fact, all those causes which may lead to neurasthenia, are important exciting factors, yet it is my conviction that syphilis is the essential cause.

It seemed to me that the proof would be afforded if I could collect a sufficient number of cases of juvenile general paralysis in which most of these exciting factors are absent and show that they were the subjects of congenital syphilis. From the numerous inmates in the London County Asylums I was soon able to collect a large number of cases of general paralysis occurring at puberty or early adolescence, and to demonstrate that clinically and pathologically they in no essential respect differed from cases occurring in adults the subjects of acquired syphilis.

Again later, I was able to collect 70 cases of tabo-paralysis and compare the same with 70 cases of tabes dorsalis, and I found among these that the parasyphilitic affection may begin with spinal symptoms or optic atrophy and terminate in general paralysis; or general paralytics may simultaneously with, or successively to, the onset of the cerebral symptoms develop tabes dorsalis, and I came to the conclusion from a research extending over three years that there is one tabes or wasting disease of the central nervous system from an etiological and pathological standpoint. One of the strongest arguments clinically in favour of this view is the fact that the Argyll Robertson pupil is for all practical purposes only met with in these post-syphilitic diseases of the nervous system. Researches in connexion with the examination of the blood and cerebro-spinal fluid, which will be referred to later, confirm this view.

According to some authorities—Bosc, Lesser, Hirschl, Nageotte, and others—general paralysis and tabes are quaternary syphilis; the former authority asserts, and with some degree of correctness, that there is a general similarity even in the lesions of general paralysis and tabes to other syphilitic lesions—viz., there is an endothelial and connective tissue hyperplasia with a tendency to fibrous and sclerous formation. But there is more than this, there is a primary neuronic decay which cannot be accounted for, solely by the changes in the supporting, enclosing, and nutrifying tissues the same as can be done in syphilitic lesions.

The view I take of the pathology of parasyphilitic affections is that in certain acquired or congenital syphilitic individuals the durability of the neurones is greatly curtailed, so that they decay and die prematurely, thereby giving rise to a series of symptoms which may be associated either with irritation of definite nerve structures—e.g., lightning pains, visceral crises, mania and epileptiform convulsions—or with neural destruction, e.g., ataxy, paræsthesia, anæsthesia, paresis, and dementia. The irritative phenomena may be the sign of increased neural irritability due to degeneration of neurones prior to their death and loss of function. I do not, however, affirm that the lymphatic and vascular changes play an unimportant part in the process of decay and death of the neurones especially in general paralysis. Now it may be asked, What is the evidence to show how this neural irritation and destruction are brought about?

It is a fact that the cases of syphilitic disease of the nervous system diminish in number and gravity with each succeeding year following infection, although it must be admitted there is no essential difference in the histological changes met with in early and late syphilis of the nervous system. It is, however, comparatively very rare for parasyphilitic affections to occur within four or five years of the primary infection, and the average time is at least ten years after the appearance of the primary sore. Seeing that the great bulk of persons are affected in youth or early manhood, so the curve of incidence of onset of syphilitic affections of the nervous system reaches its maximum somewhere between 25 and 30, whereas the curve of the incidence of onset of general paralysis and tabes reaches its maximum between 35 and 40. Whereas, on the one hand, syphilis of the nervous system produces more or less sudden obtrusive symptoms indicative of gross lesions due to meningeal irritation and vascular occlusion of a random kaleidoscopic character, with remissions and exacerbations causing new and variable paralytic and irritative phenomena, on the other hand, parasyphilitic

affections are usually so insidious in origin that it may be difficult to fix the date of the onset. Again, as a rule there is a continuous progress of the disease in which remissions and exacerbations are not nearly so manifest.

Whereas, on the one hand, syphilis of the nervous system, especially in the early stage, yields to all forms of treatment which would cause the destruction of the specific organism, on the other hand, parasyphilitic affections are seldom arrested, and though sometimes benefited by antisyphilitic treatment the degree of benefit is inconsiderable when compared with the effects obtained in syphilis of the nervous system. I have myself seen no disappearance of symptoms once established in tabes or general paralysis which could be associated with the treatment. Neither could we expect that mercury or arsenic in any form could restore neurones which have undergone degeneration, although when it is the syphilitic virus which is producing symptoms due to arterial and meningeal inflammation, the administration of these remedies gives relief by destroying the specific cause, thus arresting and clearing up the inflammatory process before neuronic destruction to any considerable degree has taken place. If the spirochæta be the cause of these neuronic degenerations in parasyphilis, how does it come to pass that it has never been demonstrated in general paralysis or tabes? whereas it has been demonstrated by many authorities in syphilitic meningitis and arteritis. It might be said that there is an intracellular granule form, but this has to be proved. So far the existence of an intracellular granule form rests only on the slender basis of analogy of the spirochæta to the tick fever spirillum which has been shown by Leishman to have an intracellular granule form. If we admit this premise then it must be assumed that the spirochæta pallida has passed into a resting stage and after a lapse of years, on an average ten, it has become active and caused inflammatory changes in the membranes, vessels, and connective tissues, with secondary irritation and destruction of the neural elements. The primary meningo-encephalitic theory was the old view of the parasyphilitic affections, but most authorities now consider that the diseases termed parasyphilitic are due to a primary neuronic decay with secondary changes in the membranes, vascular and neuroglial structures. This view was taken by Sir David Ferrier in his Lumleian Lectures on Tabes Dorsalis. The positive Wassermann reaction[2] given almost in all cases of general paralysis both by the blood and cerebro-spinal fluid would suggest that the disease was the result of active syphilis, but whereas a case of active syphilis giving the Wassermann reaction in the blood after treatment may no longer give it, this is not the case with general paralysis according to my experience. I shall therefore assume that until further evidence of a more definite nature is forthcoming to show that these late manifestations of a previous syphilitic infection are to be regarded as quarternary syphilis of a nature similar to glossitis, it will be better to accept the term parasyphilis or metasyphilia and to explain the symptoms by a premature and progressive decay of neural systems, localised in some cases to afferent systems, as in tabes, or generalised in others, as in general paralysis.

I have not time to discuss the possibility of there being a specific spirochæta for these parasyphilitic diseases, nor the question whether parasyphilis is a result of racial immunity by widespread syphilisation; nor another view, that of Neisser, that the late manifestations of syphilis in the form of tabes and general paralysis may be the result of a modification of the action of the specific organism by the widespread use of mercury. Nor will I discuss the question of anaphylaxis as an explanation, but come to the more practical side of the question of the differential diagnosis of parasyphilis and syphilis of the nervous system.

The Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System from other Diseases affecting the Brain, the Spinal Cord, and the Peripheral Nerves.

The neuroses and psychoses will first occupy my attention, for in my opinion they form a most important group of cases; important because of the difficulties arising in determining whether the symptoms are purely functional or whether they are the prodromal symptoms of grave organic disease. An individual may have had syphilis; or he may think he has had syphilis; in the former case he may deny the possibility. It is in all such dubious cases that the serum diagnosis is of the greatest value: if it is positive, there is a clear indication for treatment; if the result is negative it is often extremely useful, inasmuch as I have observed that the assurance given to the patient, that there is no active syphilis, goes a long way to improve his general condition, and the apprehension and mental distress being removed, the patient recovers from his neurasthenic condition.

The neurasthenia occurring in the secondary or active stage of syphilis is in no way specific in its symptoms, although it may be favoured and intensified by the action of the poison, but the effect on the mind of a sensitive person in whom the moral sense has received a profound shock by the acquirement of a loathsome and what he believes to be an incurable disease is a most important factor. He becomes morbidly apprehensive and he suffers in consequence with sleeplessness, loss of appetite, dyspepsia, and malnutrition, a combination of factors which terminate in neurasthenia. It is of importance to diagnose between the headache and other symptoms of such an induced neurasthenia and true syphilitic headache of the secondary period, or that more serious condition premonitory of the syphilitic affection of the membranes and vessels of the central nervous system. In neurasthenia there is little real pain; there are unpleasant sensations of tightness, heaviness, emptiness, muzziness of the head, but not true pain. In syphilitic disease, on the other hand, the pain is intense, lancinating, boring, tearing; pain which is so severe as to interfere with occupation. It is often worse at night, sometimes waking the patient at a particular time. Neurasthenic headache is generally diurnal and worse in the morning on arising and better at night on going to bed. Anti-syphilitic remedies give relief in syphilitic disease, but have no influence in neurasthenia unless the condition is due in the main to a grave anæmia of the secondary period. It is very rare for a syphilitic headache to last for any length of time without serious manifestations of organic disease occurring; in fact, syphilitic brain disease seldom strikes without warning; it may be ptosis, a squint, a transitory condition of aphasia, or paralysis, a girdle sensation, &c. In neurasthenia and hysteria there are many and varied subjective symptoms and very few, if any, objective signs of the disease.

It is important to distinguish the neurasthenic state, spinal and cerebral respectively, from tabes dorsalis in the early pre-ataxic stage when the knee-jerks may be present and from general paralysis in the pre-paretic stage. As regards spinal neurasthenia the knee-jerks are increased, there are no bladder troubles, there may be impotence, also attacks of giddiness, analgesia, and paræsthesia may suggest to the patient, especially if he have medical knowledge, tabes dorsalis, yet no physician would diagnose this disease in the absence of any of the characteristic pupil phenomena—viz., inequality, irregularity, and rigidity or sluggish reaction to light. Seeing the causes which lead to cerebral neurasthenia are in the subject of syphilis the very causes which predispose to paralytic dementia, it is often difficult to decide whether a neurasthenic displaying periods of depression or excitation, especially if he be the subject of chronic alcoholism, is or is not in the earliest prodromal stage of general paralysis; for the pupil phenomena may be absent in the earliest stages of the disease, or, if not altogether absent, are certainly not nearly so definite as in tabes.

These parasyphilitic affections may be definitely differentiated from neurasthenic conditions by an examination of the cerebro-spinal fluid. The existence of lymphocytes points definitely to a chronic inflammatory condition of the central nervous system, and I have found that in practically every case of general paralysis even in the earliest stages a lymphocytosis occurs. Moreover, it always occurs in tabes dorsalis, therefore this fact is of great importance in the differential diagnosis. Many conditions of organic disease, however, give a lymphocyte reaction. In about half the cases of tabes dorsalis the fluid also gives a positive Wassermann reaction. In practically every case of general paralysis we have found a positive Wassermann reaction. So that a neurasthenic with slight mental symptoms whose fluid gave this reaction may be said to be suffering with general paralysis in the early stage. Comparatively speaking, only about 25 per cent. of the cases of syphilitic disease of the central nervous system give a

[2] I have recently had a case in which the fluid and blood taken post mortem gave a negative reaction. Clinically the case was one of rapid general paralysis of the insane. Microscopic examination showed a very marked active and widespread destruction of the cortical neurons, marked proliferation and swelling of the capillary endothelial cells, and perivascular plasma cell infiltration though not very marked. Histologically it was an early case of general paralysis.

positive reaction, though most of them give a well-marked lymphocytosis. Some nervous persons may object to have lumbar puncture; in the case of a differential diagnosis of early general paralysis from neurasthenia an examination of the blood may suffice, for if the serum does not fix the complement and give the reaction neither will the cerebro-spinal fluid—that is to say, a negative serum reaction puts out of count general paralysis. If, however, a positive reaction of the blood is obtainable then it is necessary, in order to decide the diagnosis, to perform lumbar puncture and examine the cerebro-spinal fluid; for it is obvious that every individual who gives a positive serum reaction is not suffering from general paralysis, as it only means antecedent syphilis. It would be interesting to know whether those individuals who gave a Wassermann reaction after a systematic course of energetic treatment are more liable to these late manifestations of the effects of the virus than those who, when treated efficiently, failed afterwards to give it. I should not be in the least surprised if this were so.

Hysteria and Hystero-Epilepsy.

Hysterical paralysis and hystero-epilepsy, according to Fournier and Lang, sometimes occur in the secondary stage of syphilis, and the symptoms disappear under antisyphilitic treatment. The subjects of antecedent syphilis with a neuropathic predisposition are very liable to develop hysteria and hypochondriasis, and not very infrequently syphilophobia. A negative reaction of the blood will serve to allay their ungrounded fears and desire to be injected with "606." I have seen several such cases recently. If there is a positive reaction it denotes the necessity for treatment, and such a case as I shall describe illustrates the value of this serum reaction and the examination of the cerebro-spinal fluid.

Some years ago I treated a man with cerebral gummatous meningitis, and all the symptoms cleared up; a year later he came to me complaining of a slight pain in the left side. I told him that I hoped that it was nothing more than muscular pains, but he was to come and see me again if he were not better, as I could discover no anæsthesia or objective signs. A week later I was asked to see him by a practitioner who regarded his case as *functional*. He was paralysed in the lower extremities; it had come on somewhat suddenly. Knowing the history of this patient I took him into the hospital, and for the first few days he became rapidly worse and lost complete control over the bladder and rectum as well as complete loss of sensibility below the level of the seventh rib. Under antisyphilitic treatment he made a complete recovery. No doubt the case was one of gummatous syphilitic spinal meningitis. I am not so sure as I was once of the hopefulness of curability of syphilitic meningitis; I have seen necropsies in many cases that had apparently recovered under treatment, but which have relapsed, and I should advise all people who have once suffered with syphilitic disease of the central nervous system to have the Wassermann reaction of the blood made periodically with a view to renewal of treatment if the reaction is positive. Not that I would say if the patient showed any clinical signs pointing to syphilitic brain or cord disease, and yet gave a negative reaction he should not be treated, for we do not quite know all the conditions that may prevent the reaction occurring in some individuals. In illustration of this I may mention the following case.

A man of 35, who denied infection and showed no positive signs on his body, was admitted under my care to Charing Cross Hospital suffering with ophthalmoplegia interna and externa of the left eye; he was in a condition of drowsy stupor, and there was bilateral facial paresis; his blood gave a negative reaction by three independent and very competent observers. Nevertheless, I said this is clinically syphilis—energetic mercurial inunction treatment and iodide in large doses resulted in complete disappearance of all the symptoms in a month.

Arterio-sclerosis.

Seeing that syphilis is one of the most important factors in the production of sclerosis of the arteries, especially the cerebral arteries and general arterial sclerosis, causing Bright's disease, it follows that combined with nervous diseases may be uræmic symptoms, headaches, pyrexia, twitching, and epileptiform seizures. If uræmic symptoms occur in a case with antecedent syphilis, the blood may give a positive reaction. Now, the patient suffering with arterio-sclerosis is usually over 50 years of age, and if he has an inborn neuropathic tendency may suffer with an involutional melancholia; he becomes irritable, suspicious, and even dangerous to himself and others; there may be exaggerated emotivity and a partial dementia, so that not infrequently such cases are regarded as general paralysis. However, unlike general paralysis, the patient retains his notions of personality and his autocritical faculty, and he is more or less conscious of his failure of memory and mental enfeeblement. If he is the subject of various forms of coarse paralysis the diagnosis is easy. It is extremely rare to obtain ankle clonus and Babinski's sign in general paralysis. Lumbar puncture would settle the diagnosis in a doubtful case—lymphocytosis and a positive Wassermann reaction would decide in favour of general paralysis. Arterio-sclerosis may especially involve the perforating arteries and cause lesions about the basal ganglia, giving rise to mimic disturbances, increased emotivity, accompanied by dysarthria and pseudo-bulbar symptoms; such cases to my knowledge have been mistaken for general paralysis.

Chronic Alcoholism.

Chronic alcoholism and syphilis are so often associated that cases frequently present themselves of considerable difficulty of diagnosis. Absence of the serum reaction enables one in the absence of definite signs of syphilitic affection of the nervous system, and when all the symptoms accord with alcoholic poisoning, to exclude syphilis or parasyphilis—e.g., in polyneuritic psychosis; but suppose the reaction is positive and symptoms and signs exist which may possibly indicate general paralysis or syphilitic disease of the central nervous system combined with alcoholism and possibly masked by it. It is then that lumbar puncture and examination of the cerebro-spinal fluid will be of great use, as a lymphocytosis will show that there is, in addition to the alcoholism, a syphilitic affection; if in addition there is a positive reaction, it points to general paralysis. The following is a good case in illustration of this.

A man, aged about 28, was said to be suffering from general paralysis and I was asked to see him. I found that he had been drinking heavily for some time past; there were a great deal of mental confusion, loss of knowledge of time and place, personal illusions, and loss of memory of recent events. He had contracted syphilis five years previously, for which he had been treated. He had had a left-sided hemiplegic condition from which he had recovered: there were ankle clonus and Babinski's sign on this side. The pupils were equal and reacted sluggishly to light. I was told that his blood gave a negative reaction. I gave it as my opinion that it was not general paralysis and that he would recover with mercurial treatment and compulsory total abstinence from alcohol. I saw him again nine months later: he had two large gummata on his head, headache, and tenderness on percussion over the forehead; although he had been under the care of a medical man owing to his not complaining these had not been observed. A Wassermann gave a marked positive reaction. With mercury and large doses of iodide all the symptoms disappeared and he is practically well. A differential diagnosis of *mania a potu* from mania of incipient general paralysis associated with drink can be decided by lumbar puncture at once, although sometimes when objection is raised the true nature of the disease must be allowed to declare itself after the effects of the alcohol have had time to wear off before deciding.

Dementia Præcox.

The age, mode of onset, and evolution of this disease are unlike any syphilitic or parasyphilitic affection due to acquired syphilis, but occasionally there is a difficulty in the diagnosis of a juvenile paralytic or an imbecile the subject of congenital syphilis. There is usually in dementia præcox a strong hereditary history of insanity. Nearly 80 per cent. commence before 25. If there is any doubt, examination of the blood and cerebro-spinal fluid will settle the question.

Epilepsy with dementia, tubercular and other forms of meningitis, disseminated sclerosis, and cerebral tumours (non-syphilitic) are diseases which may sometimes be mistaken for syphilitic and parasyphilitic affections. Here, again, the examination of the blood and cerebro-spinal fluid will in most cases allow of a differential diagnosis.

The Differential Diagnosis of Syphilitic and Parasyphilitic Affections.

The average time between syphilitic infection and onset of symptoms is ten years in parasyphilitic affections; very seldom is it under five years, whereas the converse is the case with syphilitic affections. In the severe forms of syphilitic disease of the central nervous system the greatest number of cases occur in the first few years after infection and diminish with each succeeding year. Whereas the syphilitic history is well defined and the scars of lesions are common in syphilitic disease, they are comparatively rare in the parasyphilitic affections. The onset of symptoms and course of syphilitic disease are usually rapid and subject to regressions and remissions; the onset of symptoms and the course of para-syphilitic affections are usually insidious and slowly progressive, except in some cases of general paralysis in which there are numerous seizures, causing maybe *transitory* aphasia, paraphasia, monoplegias, and hemiplegias. The pupil and squint phenomena are common in syphilis, but Argyll Robertson pupil extremely rare. In parasyphilis pupil phenomena and strabismus are common, Argyll Robertson pupil is rarely absent especially in tabes and tabo-paralysis. Optic neuritis and post-neuritic atrophy are not uncommon in syphilis. A unilateral central scotoma, the other eye remaining healthy (an indication of a retro-bulbar neuritis affecting the papillo-macular bundle), is indicative of a gummatous meningitis. In parasyphilis primary optic atrophy occurs in about 10 per cent. of the cases. Bladder disturbances are common in syphilis and parasyphilis. Severe headache, worse at night, stiffness of the neck, coarse paralysis of cranial nerves, paralysis of limb and face with clonus and plantar extensor response are common as a result of syphilitic brain disease, but rarely if ever met with in general paralysis. Aphasias, anarthria, and dysarthria are common in brain syphilis, but not in general paralysis, in which the speech affection is characteristic. In fact, the term general paresis is much more correct for the parasyphilitic brain affection. The knee-jerks in a gummatous meningitis may be present one day, absent the next; in tabes they are in the great majority of cases absent throughout. The keee-jerks are exaggerated in the great majority of cases of general paralysis, but there is no ankle clonus or Babinski—in fact, these signs in a case of dementia to my mind indicate strongly syphilitic brain disease rather than general paralysis.

The Diagnosis of Tabo-Paralysis.

It is of very great importance to the patient and friends to be able to diagnose tabo-paralysis. Tabetic patients are apt to suffer with neurasthenia and mental depression and to resort to alcohol; moreover, to relieve the pains, the morphia habit may be acquired. Again, a potentially insane person may suffer with tabes and be the subject of delusions of persecution, putting an insane interpretation upon the lightning pains and visceral crises. Seeing that neither the Wassermann reaction of the blood and cerebro-spinal fluid, nor the lymphocyte reaction will help in such cases, for both tabes and tabo-paralysis give these reactions, it may be difficult to decide whether the patient is the subject of oncoming tabo-paralysis. Still, in my experience an abundant lymphocytosis and a marked positive Wassermann reaction of the cerebro-spinal fluid point to a widespread disease and therefore to involvement of the brain; if in addition in such a case apoplectiform, migrainous, or epileptiform seizures not causing gross paralysis have occurred, and especially if the knee-jerk is noted to be absent on one side and present on the other, tabo-paralysis is indicated. I may mention that about 10 per cent. of the cases of tabes dorsalis end in extension of the disease to the brain. The cerebral lesions in no way differ from those of general paralysis in the early stages.

The importance of a differential diagnosis of syphilis from parasyphilis of the nervous system cannot be over-estimated from the point of view of prognosis and treatment; whereas the former yields to energetic treatment sometimes in a marvellous manner, the latter does not. At one time I found no distinction was made in many asylums between gross syphilitic brain disease with dementia occurring in young people and general paralysis, and the cases being regarded as incurable treatment was either inadequate or not adopted. I show lantern slides of such cases.

I do not think in the light of pathology a place should be found in modern text-books for *syphilitic general paralysis*, and I speak in great deference to our leading authority, Dr. Savage, who, I believe, was the first authority in this country to recognise the association of syphilis with general paralysis and especially tabetic paralysis. There are cases of syphilitic brain disease in which there is general syphilitic end-arteritis without thrombosis; cases in which there may be at first no permanent coarse paralysis, only transitory seizures like those of general paralysis; the symptoms may be mainly psychical, although there may be headache, giddiness, and insomnia. The patient exhibits defective recollection of what has recently happened, mental fatigue, and incapacity for work; his actions are automatic and disturbances of consciousness are frequent; he may become semi-conscious or semi-comatose, then recover in almost a complete manner, only to relapse again. The transitory character of the phenomena before the occurrence of occlusion of the arteries by thrombosis resulting in permanent paralysis and dementing conditions is especially suggestive of this form of syphilitic disease of the brain. The recognition of this form of syphilis in its early stages is especially important. It is generally accompanied by a gummatous periarteritis and some meningitis more or less extensive, so that the cerebro-spinal fluid would give a lymphocyte reaction and possibly a Wassermann; the serum would almost certainly give the reaction, and should be tested in all doubtful cases. I have seen numerous cases of multiple gummatous tumours of the brain with generalised arteritis and meningitis, and the principal symptoms have been a drowsy stupor with progressive dementia, but without coarse paralysis for some time. I have noticed that such cases generally show well-marked syphilitic residua on the skin or mucous membranes, and I should always hesitate to diagnose general paresis in such cases.

Pseudo-tabes.

Cases occasionally occur of syphilitic cerebro-spinal meningitis which simulate the parasyphilitic affection very closely. I will narrate a typical case that came under my notice. A woman was sent into the wards under my care said to be suffering with tabes. She had lightning pains, girdle sensation, absence of the knee-jerks, paræsthesia and anæsthesia of the lower extremities, and bladder troubles. The pupils were unequal, irregular in outline, and sluggish to light and accommodation. There was a history of her having had a severe headache some time previously and squint and double vision. I found that she had had a healthy child four years prior to the onset of the cord symptoms, since then she had had several miscarriages. I found that the knee-jerk had come back, and I came to the conclusion that very probably, in view of the short time after possible infection, the severe headache, and the variable character of the knee-jerk, that this was a case of cerebro-spinal gummatous meningitis. Lumbar puncture was performed; 370 lymphocytes per c.mm. were found; the Wassermann reaction was negative, and the short interval, four years at most, between infection and onset made me sure that the case was one of gummatous meningitis or *pseudo-tabes*. One month of mercurial inunction treatment and all the symptoms had disappeared, and the fluid was free from lymphocytes. She still remains well, though it is now three years since I saw her first. This might have been thought to be a case of cured tabes.

Hitherto I have dealt mostly with the diagnosis of cerebral affections; I must now briefly refer to the diagnosis of spinal cord diseases.

The Diagnosis of Spinal Cord Diseases.

Syphilitic affections of the membranes may be more or less localised so as to cause practically only spinal symptoms, but many cases regarded as syphilitic disease of the spinal cord when the history of the illness and the symptoms are carefully inquired into will be found to have presented symptoms indicative of affection of the base of the brain—e.g., they have suffered with headache, a little stiffness of the neck, transitory double vision, ptosis, &c. Indeed, it is probable that cases of meningitis syphilitica, owing to invasion of the membranes by the spirochæta, may occur when the roseolar rash appears, and there have been a few cases which indicate such an affection of the membranes while the primary sore is yet unhealed. A patient presenting himself with symptoms pointing to affections of the spinal cord may give a history of antecedent syphilis and yet not necessarily be suffering from syphilitic disease of the spinal

cord. Still, as Dr. Buzzard long ago pointed out, it is astonishing how many cases of spinal cord affection in young men are due to comparatively recently acquired syphilis. I say comparatively recent, meaning thereby in comparison with tabes. The first thing to do, therefore, is to exclude syphilitic infection as a cause of spinal symptoms; the next thing is to show whether the symptoms have a causal relationship or are only coincidence. There is no clinical symptom or group of symptoms characteristic of syphilitic disease of the spinal cord, but there are certain symptoms which, if they occur in young adults, particularly of the male sex, should lead one to suspect their specific origin. The early symptoms are spinal irritation, severe intercostal pains worse at night, cramps and contracture of limb, with pains radiating down them, bladder disturbances, disappearance and reappearance of the knee-jerks, the Brown-Séquard phenomenon; in fact, symptoms pointing to a local or more generalised *meningitis* or *meningo-myelitis*, but usually without pyrexia unless there be some complication.

As in cerebral syphilis, so in the spinal disease the symptoms are particularly liable to remissions and regressions. One group of symptoms may improve or even disappear and another group appear, or symptoms may improve in one part of the body while progressing in another. These symptoms are due to a gummatous inflammation of the membranes associated generally with vascularitis involving veins and arteries. Consequently lumbar puncture and examination of the cerebro-spinal fluid reveal a marked lymphocytosis usually without a positive Wassermann reaction of the fluid, although the blood will almost certainly give it. Myelitis as a result of meningitis often follows the symptoms of meningitis; either may be focal or diffuse; the former is the more common; the latter is indistinguishable from an acute myelitis due to other causes—e.g., specific fevers, micro-organisms, and microbial toxins. The position and extent of the cord lesion may be inferred from the extent of the paralysis and loss of sensory function; the electrical reactions of the muscles will enable a judgment to be formed as to whether the anterior horns are affected. This leads me to say that cases have been described of polio-myelitis as a result of syphilis. I have had one such case under my care; the symptoms might resemble the acute spinal paralysis of the adult, especially if it were comparatively sudden in its onset, owing to the thrombosis of a vessel affected by endarteritis. Landry's paralysis might be mistaken for acute ascending myelitis of syphilitic origin, but in the latter sensation is affected, and if the patient survives there is a great tendency to the formation of bed-sores, and many muscles may waste, showing loss of faradic irritability. Such symptoms are not met with in Landry's paralysis. If the signs and symptoms point to a focal transverse myelitis we should seek to find whether it is primary or secondary. Myelitis in the acute form may arise from pressure due either to a growth or diseased bone. The root pains which precede usually by some days or weeks the paraplegia, and the absence of signs pointing to disease of the spinal column or malignant growth help in a differential diagnosis. Lymphocytosis of the cerebro-spinal fluid and a positive Wassermann reaction of the blood, even though the fluid is negative, would almost certainly indicate a syphilitic meningo-myelitis. As I have already pointed out, in most of these cases there is present or past evidence of some basic meningitis.

Disseminated sclerosis may result from multiple syphilitic foci due to obliterative arteritis; a positive Wassermann reaction of the blood, together with the age and history of the patient's illness, will suffice. A certain degree of lymphocytosis may occur in true disseminated sclerosis.

Hysteria and spinal neurasthenia in a syphilitic subject I have already referred to. The most important subject of differential diagnosis is between (1) tabes; (2) pseudo-tabes, a case of which I have already referred to; and (3) ataxic toxic peripheral neuritis; and the chief points in making a diagnosis I have summarised as follows:—

I.—*Tabes Dorsalis.*

1. Average time between syphilitic infection and onset of symptoms, ten years; very rarely under four years. Usually only slight sign of syphilitic residua. Onset and course usually slow, insidious, and progressive.
2. Pupil phenomena, inequality and irregularity common; Argyll-Robertson pupil rarely absent. Strabismus transitory or permanent, frequent.
3. Primary optic atrophy in about 10 per cent. of cases.
4. Bladder disturbances very frequent; visceral crises common.
5. Knee-jerks absent as a rule even in the early stages.
6. Lightning pains in limbs. No stiffness in neck and spine. Girdle sensation and anæsthesia to light touch in the thoracic region may be an early symptom.
7. Lymphocyte reaction as a rule not marked in the early stages. Positive Wassermann reaction in about half the cases in the cerebro-spinal fluid. Blood serum always.

II.—*Pseudo-tabes Syphilitica.*

1. Average time between syphilitic infection and most of symptoms 18 months to two years, rarely after five years. Generally signs on the body of old syphilitic residua. Onset and course usually rapid and subject to regressions and remissions.
2. Various oculo-motor paralyses common. Argyll Robertson pupil very rare.
3. Optic neuritis and post-neuritic atrophy not uncommon. Unilateral central scotoma due to affection of the papillo-macular bundle by the gummatous meningitis may occur. Headache, worse at night, often.
4. Bladder disturbances common.
5. Knee-jerks variable, one day absent and then returning.
6. Spinal pain, tenderness, and stiffness, the pains lancinating and radiating from the spine down the limbs. Girdle sensation and thoracic anæsthesia very frequently present.
7. Marked lymphocytosis of cerebro-spinal fluid. Wassermann reaction less frequent. Blood reaction always present.

III.—*Ataxic Toxic Peripheral Neuritis.*

1. A history of some toxic condition—e.g., diphtheria, typhoid, lead, arsenic, diabetes, and especially alcohol.
2. There are pain and tenderness of the limbs and paraplegia or ataxia; there may be paræsthesia; the muscles are usually wasted, and there may be reaction of degeneration. Usually there is foot-drop and wrist-drop. There is no oculo-motor paralysis as a rule, and the pupils are not affected. There are no changes in the fundus; in diphtheria there is frequently paralysis of accommodation. As a rule there is no bladder trouble unless there is an accompanying dementia. The knee-jerks may be present or absent, or exaggerated. If there be any doubt, the cerebro-spinal fluid should be withdrawn and examined. The reaction is negative and there is no lymphocytosis.

Finally, it is necessary for me to refer briefly to Erb's spastic spinal paralysis; according to my experience I am inclined to the belief of Oppenheim and Marie that these cases are really due to a syphilitic meningo-myelitis. The symptoms are a gradually developing spastic paresis of the leg, with increase of the deep reflexes; although the gait is extremely spastic the muscular contraction is but slight; the bladder is early and almost constantly affected; slight sensory disturbances are usually present. The course is chronic in most cases, and there is a tendency to improvement and even to complete arrest. Erb regarded the anatomical basis of this disease to be a primary degeneration.

The Histological Diagnosis.

Medico-legal cases may arise where a histological diagnosis is required. There have been in the London county asylums since the Workmen's Compensation Act a good few cases of patients dying in the asylums from general paralysis following injury. In some cases the injury has been slight and quite insufficient to cause the onset of the disease; in others it has been severe, and the question has arisen whether the patient was not already the subject of the disease when he met with the accident, or, indeed, whether it was not owing to a sudden lapse of consciousness the result of the disease which directly or indirectly occasioned the injury or accident. The naked-eye appearances of a well-marked case are characteristic, and I need not refer to them. The blood and cerebro-spinal fluid both give a positive reaction after death. For a considerable time past at Claybury the blood and cerebro-spinal fluid of every case that dies have been examined by the Wassermann method and the reaction is compared with the result obtained during life; all cases in which the brains are not undoubtedly to the naked eye general paralytic brains are microscoped, and we have come to the conclusion that practically every case of general paralysis gives a positive lymphocyte and a positive Wassermann reaction. A man was admitted to Claybury and died ten days after admission. He was said to have been run over by a motor 'bus three months previously and to have sustained a fracture of the thigh. He was in an acute maniacal condition, and he was certified as dying from acute delirious mania which accorded with his symptoms. I found that his blood and fluid both gave a positive reaction and there was an abundant lymphocytosis of the fluid. There were scarcely any naked-eye signs of general paralysis; in fact, there was nothing which could be asserted positively as evidence of the disease. A circumstance which accorded well with the history was that just prior to the accident he had been discharged from the navy and had passed as a taxi-driver. I found a definite scar of a chancre on the penis. Examination

of several regions of the brain was made, but only in one region examined were there the histological appearances characteristic of the disease—viz., increased vascularity, well-marked infiltration of the small vessels of the cortex with plasma cells and lymphocytes, also the membranes, proliferation of the glia cells, absence of the tangential fibres, distortion of Meynert's columns and atrophy of the constituent ganglion cells; lastly, the existence of the "rod cells of Alzheimer." All these conditions showed that this man was suffering with acute mania of general paralysis in its earliest stage; it is therefore highly probable that the severe injury had been the exciting factor in the production of the disease. We are able to decide two points by this examination—viz., that the man had general paralysis, a disease that is invariably fatal; that he had syphilis, which is an essential cause. That the evidence post mortem was to the effect that it was in its earliest stage and might therefore never have occurred if he had not had the severe accident. The fact of the existence of the scar of the chancre and antecedent syphilis should not weigh in the minds of the jury if they were satisfied that the man in all probability was not suffering with general paralysis prior to the accident, for only a very few syphilitic subjects die from general paralysis.

Another case has recently occurred which from a medico-legal point of view is of interest in showing how necessary it is to examine *various* parts of the brain histologically to confirm the diagnosis of general paralysis. Dr. C. H. Bond, of Long Grove Asylum, recently gave evidence in a trial in which the wife of one of his patients alleged that traumatism was the cause of her husband's mental breakdown. Dr. Bond considered that the case was clinically one of general paralysis of the tabetic variety, although he said there were certain anomalous bodily symptoms. He sent me the central nervous system of this patient when he died. I found a typical tabetic lesion of the posterior columns of the spinal cord. Examination of the prefrontal and central convolutions did not show the typical lesion of general paralysis. The tip of the first temporal convolution, especially on one side, showed all the characteristic lesions which I have just described.

In conclusion, I beg to thank you for so kindly listening to me so long, and yet I feel there are many things left unsaid which I might have said. However, many eminent authorities are about to follow who will be able to fill up the gaps and very probably also from their wide experience modify and correct some of the statements I have made. Finally, I wish to acknowledge my indebtedness to my assistants, Dr. J. P. Candler and Mr. Sydney Mann, who have carried out researches on the blood and cerebro-spinal fluid to which I have referred and upon which I have based my opinion as to the value of the reaction. These researches have been fully detailed by Dr. Candler in THE LANCET of Nov. 11th, p. 1320.

Nottingham-place, W.

A SPHYGMOGRAPHIC METHOD FOR THE ESTIMATION OF SYSTOLIC AND DIASTOLIC BLOOD PRESSURE.

BY J. DAVENPORT WINDLE, M.D. VICT.

THE instrumental methods in use for the clinical estimation of diastolic blood pressure are based on Marey's observation, that the maximal pulse wave occurs when the pressure about an organ is equal to the pressure within the artery supplying it. To determine the arterial pressure he devised a hand plethysmograph connected with a bottle for raising the pressure, and recorded the size of the pulse wave by means of a sphygmoscope tambour. He found that the maximal pressure corresponded with the disappearance of the pulse wave, and the minimal—i.e., the diastolic—with its largest oscillation.[1]

A similar means for estimating systolic and diastolic pressures is available by using the Mackenzie ink polygraph, and an ordinary Riva-Rocci blood pressure apparatus. The armlet is first fixed up in the usual way and connected to the manometer. The radial tambour is then applied and the pressure of the spring button carefully adjusted so that the maximal pulsation of the artery is obtained. While a tracing is being taken air is gently pumped into the bag, so that the pulse becomes progressively smaller until it ceases to be recorded; at this moment the systolic pressure is read off. Air is then released very slowly from the armlet, when the pulse wave gradually grows more ample until full pulsation is again reached. The escape of air is then stopped and the diastolic pressure read off.

This method is very convenient in the routine use of the polygraph, and sufficiently accurate for general purposes. It is a far more reliable index of actual pressure than that obtained by timing the obliteration, or moment of reappearance of the pulse by the finger. It will be found that the systolic reading is usually from 10 to 15 mm. higher than with the ordinary method, due to the fact that escape imperceptible to the finger may take place near the obliteration point. I have checked the diastolic readings by the auscultatory method devised by Korotkoff,[2] taking the diastolic pressure by this method at the moment when the sound ceases to be heard on releasing air from the bag. The maximal oscillation of the pulse curve with the sphygmographic method is true, as a rule, within 5 mm. of the auscultatory reading.

Southall, W.

PRELIMINARY REPORT ON THE TREATMENT OF THE VACCINATION SITE WITH PICRIC ACID SOLUTIONS.

BY JAY FRANK SCHAMBERG, M.D.,

PROFESSOR OF DERMATOLOGY AND INFECTIOUS ERUPTIVE DISEASES, PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE; CONSULTING PHYSICIAN TO THE PHILADELPHIA HOSPITAL FOR CONTAGIOUS DISEASES;

AND

JOHN A. KOLMER, M.D.,

PATHOLOGIST, PHILADELPHIA HOSPITAL FOR CONTAGIOUS DISEASES; ASSISTANT BACTERIOLOGIST, BUREAU OF HEALTH, PHILADELPHIA.

(*From the Laboratory of the Philadelphia Hospital for Contagious Diseases, Bureau of Health.*)

THE influence of vaccination as a protective measure against small-pox is a fact proven beyond cavil. The opponents of vaccination who deny this proposition are clearly in error. The only genuine argument of the anti-vaccinists is that vaccination is not unattended with risk. The individual risk, of course, is minute, and doubtless much less than the peril of remaining unvaccinated. But in the aggregate a considerable number of undesirable complications occur. These are in many instances due to infection of the vaccinal lesion or site subsequent to the introduction of the virus. Any procedure, therefore, which would aid in lessening wound infections should be welcomed. The best possible protection to the vaccinal ulceration is afforded by the formation of a hard, concrete crust due to desiccation of the contents of the vaccine vesicle and pustule. Such a crust will form, unless there is undue inflammation and suppuration and unless the crust is subjected to mechanical violence calculated to loosen or to detach it.

Constricting shields which make peripheral pressure about the vaccinal site lead to the formation of a friable crust easily detached by various trauma. The adhesion of the crust to the sleeve or to a piece of protective gauze will often lead to forcible decrustation when the sleeve or gauze is removed. There does not seem to be an ideal dressing for the vaccinal lesion—i.e., one that will lessen the liability of the vesicle to rupture, and one that of itself will act as an antiseptic.

In view of the property of solutions of picric acid of entering into chemical union with the keratin of epithelial tissue and thus hardening the roof of the vesicle, and in view of our experience with this drug in certain vesicular skin affections, we determined to try it as a dressing after vaccination. Synchronously with our clinical trials on vaccinated children we endeavoured to determine the germicidal value of picric acid *in vitro* and *in vivo*, as well as its penetrative qualities.

The laboratory investigations of the germicidal properties

[2] This method is described in an address by Sir Lauder Brunton, Brit. Med. Jour., Nov. 5th, 1910, p. 1390.

of solutions of picric acid were conducted in the following manner:—

Part 1.—The germicidal value of a 4 per cent. alcoholic and a 1 per cent. aqueous solution of picric acid was tested with bacillus typhosus and staphylococcus albus, and the result expressed in comparison with solutions of pure phenol, the result being known as the "phenol coefficient."

Part 2.—The germicidal power of an alcoholic solution of picric acid was then tried by applying it directly to living skin and determining the results by cultural methods.

Part 3.—An effort was made to determine the penetrating and hardening properties of picric acid in 4 per cent. alcoholic solution when applied to living skin.

Part 1.

The methods for determining the germicidal value of a substance are not entirely satisfactory. It is practically impossible to conduct a test in an ideal manner. The Rideal-Walker[1] and THE LANCET methods[2] have been employed for some years and both marked an important advance in the efficiency of such tests. Lately Anderson and McClintic[3] have modified these tests, and after an experience with all three we have decided to express the results of our experiments according to their technique, the "Hygienic Laboratory Phenol Coefficient." Considerable practice and dexterity is necessary before satisfactory and uniform results are obtained. All of the following experiments have been repeated several times. Ehrenfried,[4] assisted by Overlander, found "a 1 per cent. aqueous solution of picric acid about 50 times more active as an antiseptic than the 1 per cent. phenol." Our experiments did not show picric acid to possess anything near so high an efficiency.

Technique.—As test organisms the bacillus typhosus and staphylococcus albus were employed; the former because the Hygienic Laboratory recommends it, and the latter because it is an almost constant inhabitant of the skin. The culture of bacillus typhosus was secured from the laboratory of the Philadelphia Bureau of Health and the culture of staphylococcus albus was isolated from the nose of a patient. Both were subcultured in bouillon at least three times before being used. Twenty-four-hour-old cultures were well shaken and filtered through sterile filter paper, and one-tenth of a cubic centimetre of each was used as a dose. The disinfectant solutions were made up according to weight to assure accuracy and amounts of 5 c.c. placed in sterile test-tubes. These tubes and the tube containing the culture were cooled to 20° C. When all is in readiness the culture is added and subcultures made in extract broth with exact titration to + 1·5 — 10 c.c. in each tube, by means of platinum wire loops with a diameter of 4 mm., at intervals of 2½, 5, 7½, 10, 12½, and 15 minutes. These subcultures or seed tubes are placed in the incubator at 37° C. for 48 hours, and then examined and results noted. (See Tables I., II., III., and IV.)

These experiments show the following results. 1. With bacillus typhosus picric acid is a little over four times as efficient as phenol. 2. With staphylococcus albus picric acid is a little over three and a half times as efficient as phenol. 3. The alcoholic solution of picric acid is more efficient than the watery solution.

Part 2.

To ascertain the germicidal power of picric acid in solution when applied directly to the skin 42 children were cultured.

Such methods are far from being satisfactory, but with care some interesting data may be obtained.

Technique.—A 4 per cent. alcoholic solution of picric acid was employed, the same solution as used in the preceding experiments. The work was done during the early hours of the night when the children were in bed and asleep. In this way the danger of contamination was decreased. All cultures were taken by thoroughly rubbing an area of skin about 2½ centimetres in diameter over the upper arm with a stout platinum loop sterilised at the bedside. Inoculations were made in extract broth, + 1·5, and grown for two to four days at 37° C., when all were examined for growth. After taking a culture the picric acid solution was applied by means of sterile swabs and the part covered with sterile gauze and bound with a bandage. At intervals of 15, 30, and 60 minutes the bandage was carefully undone, a nurse lifted the gauze, and cultures were made from the same area in like manner. The skin was always scraped enough to secure a considerable portion of the superficial epithelium.

Results.—Of the primary cultures from the 42 children taken before the application of the picric acid 83 per cent. yielded growths, although it would appear that a growth should be secured under such circumstances in 100 per cent. of cases. Fifteen minutes after the application of the 4 per cent. solution of picric acid in 95 per cent. alcohol growths were secured in 22 per cent. of cases; 30 minutes after the application 33 per cent. yielded growths; 60 minutes later 51 per cent. of cases gave growths. From these results it appears that picric acid killed the organisms present in the skin in about 50 per cent. of cases in 15 minutes after application. However, if we wished to keep the skin relatively sterile it would be necessary to apply the solution at least every hour.

Part 3.

All attempts made to determine the depth of penetration of an alcoholic solution of picric acid when applied to the skin were unsuccessful. It is necessary to use fresh skin, and this we did, the solution being applied shortly before death and the specimen removed at autopsy. The same 4 per cent. alcoholic solution was used. The reason why our experiments were unsuccessful was because picric acid is soluble in all fixing, hardening, and clearing reagents. Sections of skin were frozen with ethyl chloride and carbon dioxide with unsatisfactory results; an attempt was then made to change the picric acid into a practically insoluble picrate of lead by immersing the skin in a solution of lead acetate prior to hardening and cutting, but this gave unsatisfactory results because the picric acid would dissolve into the lead solution before the picrate was formed in sufficient quantities to be of use; sections were then treated with a solution of an alkaloid (morphia and strychnia) with equally disappointing results.

Clinical Results.

The clinical trials were carried out under circumstances that were far from ideal and that were calculated to severely test the value of the method. Owing to the admission of several cases of small-pox into our hospital for contagious diseases all of the children in the neighbouring buildings were vaccinated. Among these was a number of scarlet fever cases, for the most part convalescent.

A 4 per cent. solution of picric acid in 95 per cent. alcohol was painted over and around the vaccinal site 48 hours after the insertion of the lymph. The paintings were then continued daily. Glycerinated lymph in capillary tubes manufactured by the New York Board of Health was used.

The treatment was used on 22 children varying from 1½ to 6 years of age. Of these, 20 vaccinations were successful and 2 unsuccessful. In another series of 9 cases in which the treatment was not used 7 were successful and 2 unsuccessful.

Many of the children had complications, such as nephritis, discharging ears, discharging nose, cervical adenitis, &c., prior to their vaccinations. Despite this fact, the results of the vaccinations were most satisfactory. The vaccinal course was in some cases unaccompanied by any fever or other constitutional disturbance. In several cases, on the eighth day, an evanescent rise of temperature to 101° F. occurred. The local reaction, as evidenced by œdema and the formation of an areola, varied in the different cases, but was in general less than in the untreated cases. Some of the children made no complaint of their arms at all. In most cases a firm, adherent, centrally depressed crust was formed by the fourteenth day. What impressed us most was the similarity in the course and appearance of the lesion in some cases to that of the old humanised vaccinations. One patient developed a vaccinal roseola, but there were no constitutional symptoms. In another case a little pus formed beneath the crust, but this dried up soon under antiseptic cleansing. Of the nine cases not treated with the picric acid solution one developed a severely inflamed arm with necrosis of the vaccinal site, and another had a mild pus infection of the vaccinal region.

We recognise that the number of cases in which we have employed this treatment is too small to permit of any sweeping deductions, cognisant as we are of differences in reaction from different sources of virus. We have received, however, a very strong impression that the use of picric acid solution is a valuable method of treating the vaccine site, and we trust that others will employ the method with a view to confirming or negativing our findings. We are convinced that a 4 per cent. alcoholic solution of the drug is preferable to a 1 per cent. aqueous solution. We have recently, with an idea of increasing the antiseptic properties of the solution, added 1 per cent. of iodine to it, but we have not had the opportunity of trying this out. This combination doubtless forms a trinitro-iodo-phenol which should possess strong antiseptic virtues.

We acknowledge herewith our indebtedness to Dr. A. W. Bowker, resident physician of the Philadelphia Hospital for Contagious Diseases, for valuable aid in noting and recording clinical observations.

Conclusions.

1. The use of a 4 per cent. alcoholic solution of picric acid upon the vaccinated area 48 hours after the insertion of the lymph does not interfere with the success of the vaccination.

2. We believe that this treatment lessens the degree of the local inflammatory reaction.

3. We believe that the patients are not so apt to exhibit constitutional disturbance.

4. The epithelial covering of the vaccine lesion is hardened, and there is a decreased liability of extraneous bacterial infection. This is doubtless due in part to the antiseptic properties of the solution applied.

5. We have determined by laboratory investigation that picric acid is about four times as efficient as phenol as a local antiseptic.

6. The common organisms on the skin are lessened in number by the application of solutions of picric acid.

LIVERPOOL ROYAL INFIRMARY.—The election committee at its meeting on Nov. 8th elected Dr. Frederick P. Wilson as honorary surgeon to the department for specific diseases.

A NOTE ON THE CEREBRO-SPINAL FLUID IN ACUTE POLIOMYELITIS.

BY J. GRAHAM FORBES, M.D., D.P.H. CANTAB., M.R.C.P. LOND.,
CLINICAL PATHOLOGIST AND BACTERIOLOGIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

IN view of the existence of an erroneous idea that certain outbreaks of acute poliomyelitis are due to the action of the meningococcus, and on account of the difficulty which may occur in distinguishing acute cerebro-spinal meningitis from the meningeal type of poliomyelitis in certain cases, it may be of interest to state the results of the examination of 33 specimens of cerebro-spinal fluid withdrawn by lumbar puncture from 30 cases of poliomyelitis at the Hospital for Sick Children, Great Ormond-street. The interval between the onset of illness in these cases and the date of lumbar puncture varied from three days to six weeks.

In 24 specimens the fluid was quite clear and free from clot. In 8 traces of blood were present in varying amount, and clot formation occurred according to the degree of blood contamination. In one specimen, clear on withdrawal, a very fine web of clot formed on standing. The presence of albumin was recorded in 24 specimens, but its amount was not established by means of the albuminometer. The fluid, when boiled with a few drops of acetic acid, yielded the normal faint haze in 7 specimens, a definite cloud in 3, a fine precipitate in 5, and a heavy precipitate in 6. The amount of albumin, as a rule, varied with the duration of the illness, being usually, but not invariably, more marked, either as a fine or heavy precipitate, during the first two or three weeks of illness. In one case on the third or fourth day there was only a slight haze.

Every specimen tested for sugar showed the normal trace (0·05 per cent.).

Cytological examination of the centrifugalised deposit showed usually the presence of lymphocytes slightly in excess of the normal (1–5 per c.mm.), but in six specimens there was a definite increase above the normal, and in another six no cells or only the normal very few cells were present. Very few polymorphonuclears were ever found except where blood traces occurred, when there was no evidence of leucocytosis, except in two specimens.

The relation between an increase in amount of albumin and the presence of lymphocytes in excess appears to be fairly constant, and may reasonably be taken as evidence of tissue reaction in the presence of the hitherto unrecognised virus—a reaction shown in sections, by the perivascular lymphocytic infiltration in the substance of the cord, and also seen in the spinal meninges.

Bacteriological examinations were made in nearly every case, both of film preparations of the centrifugation deposit and by culture. In no instance were organisms found in the stained films of the cells. In 23 specimens cultures proved sterile; a variety of media were tried in several—e.g., serum, serum agar, blood agar, glucose agar, glycerine agar, ordinary agar, and broth, inoculations being made both from the fluid and the centrifugation deposit, but all with negative result. In seven specimens obvious contaminations were present.

Post-mortem examinations were made of two fatal cases. In one, in which the cerebro-spinal fluid six weeks previously had been normal and sterile, a streptococcus was obtained from the spinal fluid, but films and cultures from the cord itself proved negative. In the other the cerebro-spinal fluid, which had been normal and sterile during life, yielded no growth. There was, however, early mitral valvulitis and a small infarct was found in the kidney. The heart's blood proved sterile. In these two cases there was, therefore, evidence of a secondary terminal infection.

In 10 cases Widal's serum reaction was applied to B. typhosus and B. enteritidis (Gärtner), but in all it proved negative. This was done in view of an article on "The Etiology of Poliomyelitis," by A. E. Vipond, who obtained a positive reaction in 6 out of 16 cases occurring in Montreal and attributed the disease to the action of B. typhosus.[1] Blood films have also been examined for the Dixon-Fox-Rucher organisms in several cases without success.[2]

[1] Brit. Med. Jour., March 18th, 1911.
[2] Brit. Med. Jour., Epitome, p. 44, March 18th, 1911.

Leucocyte counts in three cases gave 10,750, 11,000, and 12,000 per c.mm. respectively. Differential counts: Polymorphs, 56 per cent.; lymphocytes, 41 per cent.; and large mononuclears, 3 per cent.

There can be little doubt of the value of lumbar puncture as an aid to diagnosis between cases of acute cerebro-spinal meningitis and acute poliomyelitis of the meningeal type. In the former the fluid shows very unmistakeable characters, marked turbidity, frequently coarse, purulent clot formation, a great excess of albumin, absence of dextrose, a copious cell deposit of polymorphonuclears, and easy recognition of the meningococcus both in the film preparations and cultures on serum—characters which I have verified in some 200 examinations.

Mill Hill, N.W.

RUPTURE OF THE POPLITEAL ARTERY AND VEIN; DIFFUSE HÆMATOMA.

BY DOUGLAS DREW, B.S. LOND., F.R.C.S. ENG.,
SENIOR SURGEON TO THE QUEEN'S HOSPITAL FOR CHILDREN, BETHNAL GREEN, E.; CONSULTING SURGEON TO THE HOUNSLOW HOSPITAL.

THE following is a brief account of the case, which I saw in consultation with Dr. L. de B. Christian of Hounslow on May 19th, 1911.

The patient, aged 28 years, was admitted to the Hounslow Hospital on April 25th, having been run over by a waggon, the wheel of which passed over the thigh just above the knee. There was a lacerated wound to the inner side of the patella, as well as considerable swelling around the knee, accompanied by much pain in the leg. The wound was cleansed and dressings were applied. On the sixteenth day after the injury the wound, which was granulating, was drawn together with a few sutures. At the end of three weeks the pain in the limb, which had persisted, became suddenly very severe and the swelling around the knee increased in size and œdema of the leg developed, but at no time had there been any coldness or cyanosis of the limb.

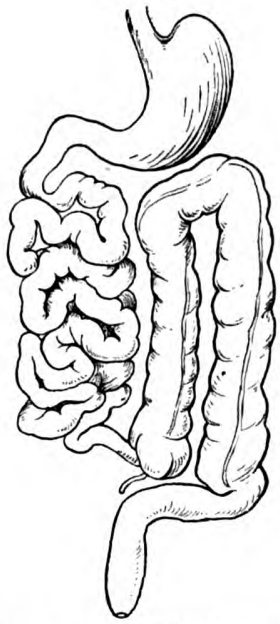
When I saw the patient for the first time on the twenty-fourth day after the injury he was very anæmic and was enduring very severe pain, which had to be relieved by morphia. The whole limb was greatly swollen, and below the knee there was marked œdema, which rendered it impossible to determine whether there was any pulsation in the tibial vessels. The region of the knee was enormously swollen, particularly posteriorly, where the swelling, which was hard, felt hot, the temperature being 101° F. No pulsation or thrill could be made out. It was quite clear that operative treatment was needed, as from the inflamed condition it was suggestive that the hæmatoma in the popliteal space had become infected, and the history was suggestive of rupture of the popliteal artery.

The operation was performed on May 21st. A tourniquet was applied to the groin and an incision about 10 inches in extent was made on the inner side of the knee and thigh. 1¾ lb. of blood clot were turned out of the popliteal space, and after the cavity had been sponged clear of it the popliteal vein was seen hanging across the space as a thick thrombosed cord. The upper end of the artery was at once discovered as it emerged from Hunter's canal, where it had evidently been crushed against the shaft of the femur; at this spot it was found that the popliteal vein was also partially torn through. Some little difficulty was experienced in finding the lower end of the artery, which had retracted about 4 inches to the lower part of the space. Both ends were ligatured with fine thread without division of the coats, the upper end being drawn down before the ligature was applied, so that it might retract into Hunter's canal. The wound was closed and free drainage was provided. At the end of a week, as had been anticipated, some suppuration in the cavity occurred, possibly from infection spreading from the adjacent wound at the inner side of the patella, but things went well until June 11th—i.e., 21 days after the operation, when the temperature rose and the patient complained of severe pain in the knee-joint, which became very hot and swollen, and was evidently infected. The joint was freely laid open by lateral incisions and drained. A few days later, as the temperature still remained high, a tube was inserted into the joint from the posterior aspect; it was then discovered that the infection of the joint had arisen through

sloughing of the posterior part of the capsule over the internal condyle of the femur. From this date the patient made steady progress towards recovery, and is now walking about with good but somewhat limited movement of the knee joint.

Apart from the comparative rarity of subcutaneous rupture of a main artery and vein, the case under consideration presents several points of interest. From the history it is clear that although a certain amount of bleeding into the tissues occurred at, or shortly after, the injury, yet the very severe hæmorrhage did not come on until three weeks later, as is evidenced by the sudden increase of the swelling and of the pain. It must, I think, be a very unusual occurrence for a clot to become displaced at so late a date while a patient is lying quietly in bed. Injury of this nature, particularly when the vessel affected is in the lower limb, is usually followed by threatened gangrene, and when it is the popliteal that is injured gangrene almost invariably follows. Schorong collected 45 cases of injuries of this nature to the main arteries. Of this number the popliteal was affected in 20, and in all of them gangrene supervened; in 11 the femoral was injured, and gangrene followed in 7; and in 2 the iliac, and both terminated in gangrene. The remaining 12 occurred in the arteries of the upper limb. It is difficult to offer any explanation why our patient was so fortunate as to escape, unless it was due to the absence of severe hæmorrhage into the tissues at the time of the accident. In this connexion it is interesting to note that there was not even coldness or cyanosis of the limb.

Doubtless the fact that the severe hæmorrhage did not occur until the end of three weeks, by which time the collateral circulation was well established, accounts for the fact that gangrene did not threaten after its occurrence. If it had been possible to diagnose the condition at the time of the accident one might have tried to restore the continuity of the artery by suture, but at the time of the operation it was clearly unnecessary, as the collateral circulation was well established. It is probable that the hæmorrhage came from the distal end of the artery, as the proximal end was found to contain a decolourised clot; the distal end was not examined as it lay in the depth of the wound, and was difficult to reach to apply the ligature.



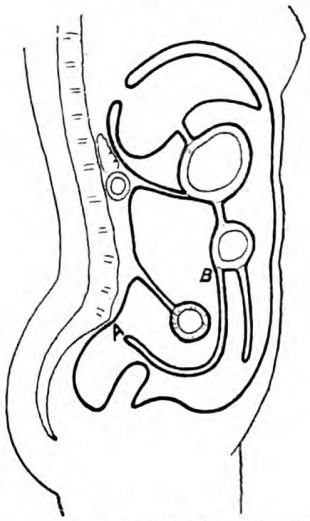
Wimpole-street, W.

TWO RARE ABNORMALITIES OBSERVED IN THE COURSE OF OPERATIONS.

BY JOHN D. MALCOLM, F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

CASE 1. *Operation for removal of the vermiform appendix; the colon all on one side.*—A woman, aged 43, who was admitted to the Samaritan Free Hospital, had suffered recently from an illness attributed to appendicitis and complained of persistent pain in the cæcal region. Chronic appendicitis was diagnosed, but when the abdomen was opened the cæcum was not in its usual place. On the supposition that it had not descended a second incision over the liver edge was made, and still neither cæcum nor colon was discovered. The gall-bladder and ducts were bound down to the stomach and liver by inflammatory adhesions, but no stone was felt and the bile could be squeezed out of the bladder, proving that the cystic duct was not occluded. Coils of small intestine, which were not adherent, filled the space where the colon should have been. The second portion of the duodenum was apparently normal. Its last part was provided with a mesentery and lay in the right hypochondriac region. A short omentum was seen attached to the stomach. By a further examination through the first-made incision the cæcum was found on the left side of the body, as low in the abdomen as usual, and so mobile that it could be brought well into view. The small intestine entered it from its right side and the appendix sprang from just below the ileo-cæcal valve. The appendix was bound to the cæcum by adhesions which did not appear to be recent. After removal of the appendix the sigmoid flexure was found to the left of the cæcum. Thus all the small intestine was to the right of all the colon. The conditions are diagrammatically represented in Fig. 1, but the height of the colon in the abdominal cavity was not determined. Sections of the appendix showed that its mucous and submucous coats were inflamed, but it is not proposed to discuss the question whether inflammation of the appendix lying on the left side of the body or inflammation of the bile-ducts could have been the cause of the symptoms attributed to appendicitis. The patient was in good health for about 18 months after the operation, and then came back complaining of vague abdominal pains, which were relieved by simple remedies. A proposal to have the abdomen photographed by X rays after a bismuth meal was declined and she did not return. It is obvious that in this patient the half-twist of the alimentary

FIG. 1.



canal by which in the course of development the ascending colon passes over to the right side of the abdomen did not take place. I am not aware that this malformation has been described before.

CASE 2. *Gastro-jejunal anastomosis for secondary cancer involving the stomach; small intestine shut off from the general peritoneal cavity by a peritoneal membrane.*—In 1905 I removed the cancerous left mamma of a woman who was then 55 years of age, and she apparently made a complete recovery. About June, 1910, she began to suffer from pain in the back of the chest which extended towards the throat and was accompanied after a time by vomiting and a formation of two large swellings lying side by side in the upper two-thirds of the abdomen. These were resonant on percussion and varied in size with the food taken and the material ejected by vomiting. The patient was under the care of Mr. R. Capes of Denmark Hill, who kindly wrote to me about her, but she refused to see me again until February, 1911, when in consultation a diagnosis was made of secondary malignant growth involving and obstructing some portion or portions of the upper part of the alimentary canal. Surgical treatment was not thought desirable unless the conditions became intolerable, in which case it might be wise to attempt to short-circuit the intestine past the obstruction.

After a few days the patient was determined at all hazards to get any relief that was possible at once. Accordingly, on Feb. 15th Mr. Capes administered an anæsthetic, and I operated with the assistance of Dr. Andrew Elliot. Immediately before the patient was placed upon the table a large quantity of fluid was washed out of her stomach, so that this viscus when exposed was small and flaccid. It had a somewhat hour-glass shape, and the two swellings observed before the operation had been its distended right and left portions which had doubled down from the narrow part so as to make a valve-like division between them. Behind there was a diffuse new growth, apparently of retroperitoneal origin, which fixed the upper narrow part of the stomach to the posterior wall

of the lesser peritoneal sac, and which just showed itself on the surface of the greater cavity of the peritoneum above the lesser curvature of the stomach. The ascending, transverse, and descending colons appeared normal, but when the omentum was turned up there were no small intestines visible anywhere. In their place there was a soft elongated oval mass lying more or less parallel with the long axis of the body. When its lower end which dipped into the pelvis was brought through the incision this mass assumed a rounded shape. It consisted of a thin membrane of peritoneum covering the whole of the small intestines and bulged by them into all parts of the peritoneal sac which they usually occupy. The membrane (A, B, Fig. 2) was attached to the posterior

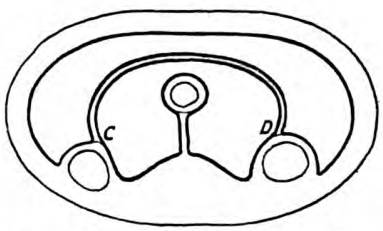


FIG. 2.

Abnormal membrane. A B, In longitudinal section; A marks the nearly central round opening in the membrane.

abdominal wall transversely above the sacral promontory, and close to this attachment there was a gap in it at A, Fig. 2, through which the small bowel passed just before it joined the colon. This opening had a diameter of about an inch and its edge was thickened. The abnormal membrane was incised and afterwards cut away and then the small intestines were exposed and appeared to be in all respects normal. The relations of the upper end of the jejunum were those usually found. The membrane which had been incised extended up to the transverse colon, to the back of which it was attached. Above the colon another or the same membrane was continued to the stomach across a space of quite 2 inches. From the stomach a membrane passed to the posterior abdominal wall in the usual position of the lower limiting boundary of the lesser sac of the peritoneum. The abnormal membrane was attached at the sides (C, D, Fig. 3) to the

FIG. 3.

Abnormal membrane. C D, In cross section.

posterior wall of the abdomen inside the attachments of the ascending and descending colons, which were rather more loosely fixed than usual. Figs. 2 and 3 show the relations of the parts diagrammatically in longitudinal and in cross sections as well as it was possible to define them in the living body.

A short circuit was made between the left portion of the stomach and the jejunum, and as the gastric wall was fixed posteriorly an anterior anastomosis was made, the small gut being brought through the thin membrane between the stomach and the colon. Shock was severe towards the end of the operation and the administration of the anæsthetic had to be discontinued, but Mr. Capes kept the patient going and she rallied. In spite of frequent vomiting for a few days progress was rapid, and after a fortnight the patient was able to be up and about. She became so well that she expressed the belief that she was cured. But on July 7th she again consulted Mr. Capes because she had become deeply jaundiced. He found a large irregular mass occupying the greater part of the abdominal cavity, the left iliac fossa being most free from growth. The tumour increased in size and the patient soon had to take to bed, becoming gradually weaker until she died, on Sept. 2nd. During the last fortnight of her life there was almost incessant diarrhœa, but apart from this there were no fresh symptoms. There was no pain and no vomiting. The results of the operation were therefore very gratifying, for the patient had quite four months of active life and she died a much easier death than that accompanied by obstructive vomiting.

Dr. J. W. Walker, of Peckham Rye, who first sent this patient to me, and under whose care she was for many years, has kindly told me that she had never suffered from any illness attributable to an inactivity of, or obstruction to, intestinal peristalsis, and, of course, the abnormality found, apart from the new growth, would not cause symptoms of any kind.

Professor Cleland in 1868[1] described a condition observed post mortem which very closely resembled that above described. When the abdomen was opened "the entire mass of the small intestine remained concealed from view, being lodged within a secondary sac bounded by omentum and mesocolon and communicating with the general sac by means of a small aperture at the upper margin of the ileo-cæcal junction only large enough to admit the passage of a finger." On making incisions from this natural inlet to the arch of the colon "the normal arrangement of peritoneum may be said to have been produced."

Another example of a somewhat similar abnormality was found in the post-mortem rooms of the University of Manchester by Dr. J. D. Hickley and Dr. J. Cameron.[2] In this case the enveloping membrane did not have any opening and it was quite separate from the colon. It contained in its upper anterior part the lower portion of the duodenum, which lay in front of the superior mesenteric artery. The relations of the abnormal membrane to the colon and duodenum in this case appear to have been quite different from those found in the other two.

ROYAL SOCIETY MEDAL.—A Royal Medal has been awarded by the president and council of the Royal Society, with the approval of the King, to Dr. William M. Bayliss, F.R.S., &c., for his researches in physiology.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14th, 1912, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the College on or before May 1st, 1912. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga Prize for 1911 has been awarded to Dr. Francis D. Patterson, of Philadelphia, Pa., for his Essay entitled "The Parathyroid Glandules."

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Treatment of Cholera.

A MEETING of this section was held on Nov. 10th, with Sir WILLIAM OSLER in the chair.

Major LEONARD ROGERS, I.M.S., read a paper entitled "Further Experience of the Treatment of Cholera by Injections of Hypertonic Salines and Permanganates Internally among Europeans at Palermo." He said that in Calcutta he had found cholera to be more severe and more difficult to treat successfully in Europeans than in natives of India, so he had spent most of last August studying the question in the lazaretto at Palermo, with the kind permission of the Italian sanitary authorities and of the director, Professor Romano. Major Rogers claimed that his researches on the blood changes in cholera had shown that the death-rate was in proportion to the loss of fluid from the blood, which amounted in the collapse stage to from one-half to two-thirds of the entire fluid of the serum, while the salts might be lost to a still further degree. About four pints of hypertonic solution must be injected intravenously to replace these losses. Normal saline solutions had been found to be of little use, as they rapidly escaped again through the bowel with return of the collapse. By using a hypertonic solution containing at least half as much chlorides again as a normal solution (120 gr. of sodium chloride to one pint), the fluid was retained in the body, and the diarrhœa was usually checked. By that simple means the death-rate in Calcutta was reduced from 60 to 33 per cent. Still the worst cases died from toxæmia, so Major Rogers experimented further and found that cholera toxins were readily destroyed by oxidising agents. He therefore gave large quantities of permanganates internally, with the result of still further reducing the death-rate to only 23 per cent. in native patients. Still more striking was the fact that whereas there was evidence to show that not more than 10 per cent. of seriously collapsed cases used to recover, no less than 68 per cent. of such cases had been saved by the new methods of treatment. With Europeans at Calcutta the recovery-rate for 13 years under the old treatment was only 18·4 per cent., while with the new methods it rose to between 50 and 60 per cent., a great advance, yet one still leaving room for further improvement. During the reaction stage which followed recovery from collapse, the great dangers were high temperature and deficient renal secretion leading to uræmia. The latter Major Rogers showed to be due to deficient blood pressure and continued concentration of the blood, which could nearly always be prevented, if the kidneys were previously healthy, by removing those conditions by additional isotonic saline injections and blood-pressure raising drugs. The proportion of uræmic deaths after cholera in Calcutta had been reduced to one-half by these measures. During the three weeks Major Rogers lived continuously at the cholera hospital at Palermo 84 intravenous injections were given in 67 patients, at nearly all of which he was present. During the first ten days, when the difficulties were exceptionally great and time only permitted the more severely collapsed patients to be transfused, 51·8 per cent. of 27 cases were saved from almost certain death. This series included four very old patients who were hopeless from the first, an unusually large proportion. During the last 12 days, when the medical staff had learnt his methods and were able to give him most valuable assistance, the recovery-rate among 40 very serious cases treated by intravenous injections was just 60 per cent., which was distinctly better than had previously been obtained in collapse cases among Europeans in Calcutta, and represented a six-fold reduction in the mortality among that grave class of case. Further, with more time and help and the English system of nursing several more cases might, he was sure, have been saved. The death-rate among the total admissions during his stay, he was informed by the director, was under 20 per cent., but as this included some doubtful suspected cases Major Rogers did not lay so much stress on it as on the rate in the very serious intravenous cases. Gratifying as these results were, he was convinced by his probably unique experience at Palermo that they would be improved on in the future. Hitherto, he had gone on the principle of only giving intravenous injections when the blood pressure had fallen as low as 70 mm. or less in natives of India, or 80 mm. or under in Europeans, unless the blood was found to be extremely concentrated, as shown by a very high specific gravity. Experience showed that a fair proportion of cases not requiring an intravenous injection on admission subsequently collapsed, and might be ultimately lost in spite of intravenous saline solutions being then administered. He had thus often had to regret abstaining from giving an intravenous saline solution on admission in a not very serious condition. On the other hand, he had never regretted having given an injection, so it was evident he had not yet used them as often as was advisable, and earlier and more frequent intravenous injections were clearly indicated. Fortunately there was in the specific gravity of the blood a safe guide, for if it was raised from the normal of 1056 to over 1062 he had always found it safe to give three or four pints of hypertonic saline solution intravenously in adults. In future in cholera he intended to use these injections in all patients in the acute diarrhœal stage with a specific gravity of the blood over 1062 and a blood pressure below 100 mm. in an adult in order to anticipate and prevent the onset of collapse, and he was sure that by this means many of the deaths from late complications, such as uræmia, asthenia, and lung complications, would be averted. In patients coming fairly early under treatment, and who were neither old (over 50) nor very young, and whose kidneys were healthy, he was convinced that the mortality might be reduced to an extremely low figure, probably to under 20 per cent. In very young children subcutaneous injections of hypertonic salines were frequently successful in preventing or even removing collapse, while a number of children between the ages of 6 and 11 years in a collapsed condition were saved by the same solution given intravenously. His hypertonic solution would therefore appear to be worthy of trial in infantile diarrhœa, especially if the quantities given were regulated by estimations of the specific gravity of the blood by means of glycerine and water solutions as used by him in cholera.

Dr. F. M. SANDWITH said that for Major Rogers to have brought down the mortality of cholera from its usual 60 per cent. to 23 per cent. or even 20 per cent. in India was a great achievement. Dr. Sandwith was glad to hear of a ready means of getting the specific gravity of the blood, because it must be remembered that the majority of cases of cholera had to be treated in cholera camps and villages without any of the resources of the laboratory.

Surgeon-Major WILLIAM DUNCAN, I.M.S., said that when he was in India his mortality from cholera was 60 per cent. of the cases, so it seemed to him almost incredible that it could have been brought so low as had been stated, but in many epidemics there was a low percentage of recovery following on a higher percentage. Moreover, Dr. Rogers's experience rendered his figures trustworthy.

After Mr. E. C. HORT had spoken Major ROGERS replied.

LARYNGOLOGICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Nov. 3rd, Dr. STCLAIR THOMSON, the President, being in the chair.

The PRESIDENT showed a case of Epithelioma of the Larynx in a man, aged 23, which had been exhibited at a previous meeting of the section and in which the appearances suggested a simple rather than a malignant growth. The subsequent course of the case, together with the microscopic examination, however, had rendered the diagnosis certain.

Mr. J. EVERIDGE exhibited a Pedunculated Intrinsic Growth of Larynx in a man, aged 41, attached to the free margin of the posterior fourth of the right vocal cord, and freely moveable during respiration.—Various opinions were expressed by the members as to the nature of the growth, and it was agreed that microscopic examination alone could be relied upon for certainty.

Mr. HERBERT TILLEY showed two cases illustrating Unusual Complications of Chronic Empyema of the Nasal Accessory Sinuses. In one, a fluctuating swelling at the inner margin of the orbit had induced displacement of the

eyeball downwards and outwards; operation revealed destruction of the roof of the orbit and of the posterior wall of the frontal sinus. The second case presented proptosis of the right eye with œdema of the upper eyelid and cheek. A fistula, discharging pus, led to carious bone in the inner and posterior region of the orbit. The parts having been opened up from the orbit the ethmoidal wall was found to be diseased, and a sequestrum was removed from the region of the posterior cells. Operation on the antrum showed this cavity to be full of thick caseous pus.—Discussing the second case several members remarked that the presence of thick pus in the antrum was probably induced by the sequestrum, since it had been remarked that the condition known as rhinitis caseosa was often found in conjunction with a foreign body in the nose.

Mr. TILLEY also showed a patient with Nasal Polypi, in whom there was an erosion or deficiency of both nasal bones.

Mr. G. WILKINSON exhibited a case of Melanotic Sarcoma of the Nose. The patient was a man, aged 51, and the sarcoma consisted of a rounded projection growing from the vestibule and lateral nasal wall, and a polypus of sooty-black colour attached to the middle turbinal. The soft tissues of the side of the nose, cheek, and upper lip were infiltrated by the growth, and the septum showed melanotic infection at the spot where the growth came into contact with it. This extensive involvement had necessitated complete removal of the left upper jaw, together with the soft parts covering the left side of the nose externally, as well as the skin of the ala and a portion of the upper lip and cheek. The gap thus left was subsequently closed by a plastic operation. The operation, performed a year ago, had not so far been followed by any recurrence.—Members drew attention to the extreme rarity of melanotic sarcoma of the nose.

Mr. WILKINSON also showed a Fibro-angioma Growing from the Inferior Turbinal, of the same type as that which was commonly termed "bleeding polypus of the septum."—Several members agreed that this and other cases, however, should lead to the adoption of the expression "bleeding polypus of the nose" as a more accurate title of this variety of neoplasm.

Dr. H. LAMBERT LACK showed a case of Papilloma of the Palate in an old man, with microscopical section of the tumour, the clinical aspect of which had aroused suspicion of malignancy, a suspicion which was, however, removed by the microscopical examination.

Dr. W. H. KELSON exhibited a case of Ulceration at the Base of the Tongue. He was disposed to regard it as tuberculous, although several members raised the question of malignancy.

Dr. KELSON also showed a case in which the appearance of the tonsils and fauces bore some resemblance to the appearances seen in secondary syphilis affecting those parts.—Several members had seen similar cases, and the suggestion was made that the habit of drinking strong alcoholic liquors might be responsible for the inflammatory exudation present.

Dr. DAN MCKENZIE and Mr. HENNING JAMES showed a case undergoing Rapid Expansion of the Jaw by means of dental plates and screws, for nasal obstruction due to narrowed nasal passages, a method which has been used in America with considerable success according to the reports.

Dr. JAMES DONELAN exhibited a case of Laryngeal Tuberculosis (shown also in May, 1909, and June, 1910) in which repeated applications of the galvano-cautery had been of considerable service.

Dr. DONELAN also showed a woman suffering from Multiple Sinusitis in whom the frontal sinus had been opened three times. On the third occasion the sinus was found to have become filled with bone.

Dr. ANDREW WYLIE showed a case of Paralysis of the Right Vocal Cord, with an affection of the third, sixth, and tenth motor cranial nerves, with a negative Wassermann reaction. The causation of the nerve lesions was problematical.

Mr. GEORGE W. BADGEROW showed a girl with a Lingual Thyroid and a patient with Cyst of the Ary-epiglottic Fold. In neither case was operation advised.

Mr. BADGEROW also exhibited a Swelling in the Neck of a Child, aged 4½ years, which seemed to members to be a cystic hygroma.

Dr. W. JOBSON HORNE showed a case of Ulceration of One Ala and Vestibule of the Nose, which reminded the PRESIDENT of a class of pernicious ulcers in this situation described by McBride, and not amenable to treatment.

Dr. G. WILLIAM HILL and Mr. C. HOPE showed two cases of Cancer of the Œsophagus, in which arrest of food took place in the deep pharynx, although the site of the growth lay well below the bifurcation of the trachea.—A discussion upon the question of œsophageal spasm followed the exhibition of these cases.

Dr. HILL also showed a child in whom Laryngo-tracheostomy had been performed.

Dr. J. DUNDAS GRANT exhibited a case of Early Epithelioma of the Ventricular Band in a man aged 30, in which both the clinical appearances and the microscopic section gave rise to some differences of opinion.

Mr. W. D. HARMER showed a patient, aged 46, with Superficial Ulceration of the Fauces, Palate, Tonsils, Pharynx, Cheeks and Lips, suggestive of pemphigus for streptococcal infection. The skin was not affected, but one eye had been destroyed.

OPHTHALMOLOGICAL SOCIETY.

Dust-like Opacities.—Ocular Conditions found in Mongolian Idiots.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 9th, Mr. J. B. LAWFORD, the President, being in the chair.

The PRESIDENT announced that some time ago the Council determined to propose three names of gentlemen for honorary membership: the late Dr. Hughlings Jackson, Sir Jonathan Hutchinson, and Dr. Landolt, the Bowman lecturer of last summer. The result of the ballot was the unanimous election of Sir Jonathan Hutchinson and Dr. Landolt.

Professor STRAUB read a communication on the Pathology of Dust-like Opacities in the Vitreous Body and of Descemet's Dots, and it was supplemented by an epidiascope demonstration. He said that among the diseases of the eye there should be recognised an inflammation of the vitreous body which he proposed to name "hyalitis." He injected into the vitreous body of the rabbit some pathogenic microbes. Those microbes made the culture there and only there, and attracted to the vitreous body serum and leucocytes. The serum and leucocytes were produced by the vessels of the ciliary body, but that was not a reason to talk of cyclitis in cases of inflammation of the vitreous body. He likewise injected into the ciliary body pathogenic microbes, and to those went serum and leucocytes, and there was produced a real cyclitis, quite different from the hyalitis which he had in the first experiment. In the laboratory hyalitis could be distinguished from cyclitis, and the same distinction should be made in practical work. But that had not yet been done. The two diseases were mixed up in the text-books. The books said the ciliary body poured out its exudate into the vitreous body, but that was a mistake, as leucocytes did not allow themselves to be poured out. Metchnikoff said that leucocytes only went where they were attracted by chemotactic substances. When there were microbes in the vitreous body those substances went towards the vitreous body; when microbes were in the ciliary body the leucocytes went to the ciliary body. He had, in order to test the matter, tried to produce inflammation of the ciliary body by infecting the ciliary body with tubercle bacilli, causing in that way granuloma. He then made sections to see whether the vitreous was clear. He thought it was clear, with the exception of a few leucocytes here and there. But when making sections through the eye he found that the optic nerve was somewhat swollen, and that in its cup there were many leucocytes, and those were projected on to the immediately adjacent retina. So he concluded that tubercular granuloma in the ciliary body had the power to cause a very slight inflammation of the optic nerve on the other side of the eye. The lymph stream in the eye went from the ciliary body to the optic nerve, and took with it some toxins which were produced by the granuloma. Those experiments were made 20 years ago. He did not feel satisfied with his method of infecting the ciliary body, therefore eight years ago he recommenced, with a colleague, a new series of experiments, in which a thread charged with tubercle bacilli was passed through the ciliary body, through the sclerotic, and through the superficial layer of the ciliary body, and brought out into the sclerotic again. The thread was cut at the points of entrance and exit, so that there remained in the ciliary body a piece of thread 3 mm. long, and after 10 to 14 days a granuloma commenced. Some

weeks later the eye was extirpated and sections made, and he found the same things as in his experiments 20 years ago. He showed colour photographs exhibiting the points he had mentioned. The dots were caused by groups or heaps of leucocytes. Among 14 cases of dust-like opacities only one was syphilitic, nine were tubercular, and the remainder he did not know the nature of. It was quite clear that Descemet's dots were groups of leucocytes. The vitreous body, he felt sure, obtained no leucocytes from the cornea; in inflammation of the vitreous body the leucocytes came from the vitreous body.—The PRESIDENT thanked Professor Straub for his able exposition, based upon prolonged and numerous experiments.—Mr. E. TREACHER COLLINS asked how the leucocytes which died got to the back of the cornea in the first place.—Mr. J. HERBERT PARSONS said he understood Professor Straub's contention to be that the leucocytes were carried forward in the lymph stream, and his explanation of the formation of the dots was a very ingenious one. But the speaker criticised the use of the terms "hyalitis" and "descemetitis," as he regarded their use as backward steps in pathology. The tissue under discussion was non-vascular and apparently passive, whereas inflammation was pre-eminently an active process. He had hoped Professor Straub would have supported the view which he, Mr. Parsons, had hypothesized, that where there were dust-opacities in the vitreous associated perhaps with choroidal change there was really a low grade of cyclitis going on to account for the presence of those opacities, and that they were not due to any inflammation present in the vitreous *per se*. Supporting that view was the fact that in cases of choroidal inflammation there was no transference of leucocytes or organisms directly from the choroid into the vitreous until the membrane was burst through.—Mr. W. H. JESSOP said Professor Straub did not appear to have made quite clear what he understood to be the difference between hyalitis and cyclitis. He had been much interested in the demonstration of leucocytes in the cup of the optic nerve and the slight degree of papillitis. That was particularly interesting because one often felt there must be some papillitis because of the degree of swelling.—Professor STRAUB replied, affirming his belief in his ultimate power to convince ophthalmic surgeons of the truth of his thesis when he came to publish the full results of his work. He relied for the acceptance of his views upon a combination of the histological and clinical material which he had collected.

Mr. A. W. ORMOND read a paper on Ocular Conditions found in Mongolian Idiots. He had examined a number of these cases at Earlswood and Darenth Asylums, at the Evelina Hospital, and elsewhere, in all 43 cases. He described the facial and physical traits. They had a certain liability to particular diseases. Over 50 per cent. had a defect in their lenses, and almost all had some ocular defect. Sometimes Mongolians could be recognised as early as the second year. When seen later they were short of stature, due mainly to the shortness of the limbs. The head was round and the occipital protuberance of the skull ill-developed. The hands were small and the thumbs squat, the little finger being incurved. The foot was flat, and the subjects often sat tailor-fashion. They had a difficulty in pronouncing certain consonants. They were imitative, fond of music, and affectionate. Most of them died from tuberculosis, and they did not often attain adult life. There was almost constantly some ocular trouble present—blepharitis, ectropion, squint, nystagmus, or lens opacity. Blepharitis and conjunctivitis might be primarily due to dirty habits, and might be kept up by uncorrected errors of refraction. A more certain cause of the inflammatory condition of the lids was a dry, glazed condition of the skin of the lower lids, which by its contraction caused a slight degree of ectropion. In more than 50 per cent. of his cases some form of lens opacity was present, and with such a high proportion it might be regarded as an aid to diagnosis. The cataracts were of the incomplete form, and most of them of the "dot" variety in the position common for lamellar cataract. These dots when slight were often translucent, and so could not be seen by transmitted light. The opacities did not reach to the periphery of the lens in any direction, and consisted of numerous small discrete dots. The posterior pole of the cataract was often marked by a star-shaped opacity. Though the teeth of these people were defective they did not show the honey-combed condition so frequent in cases of lamellar cataract. Mr. Ormond could not record accurately the visual acuity, as the children were not sufficiently controllable to be trusted with glasses. The youngest of the patients showing cataract was aged 6½ years and the oldest 43, the average being 14¾ years. Mongolian imbeciles were in many cases the children of old parents or the last child in a large family. Of his 42 cases, 32 were males and 10 females. 23 had the interpalpebral fissure directed upwards and outwards, five had nystagmus, nine had squint, 18 had either blepharitis or ectropion, or both, 11 had epicanthus, and 25 had some lens opacity.

The following cases and specimens were shown:—

Mr. R. FOSTER MOORE showed a case of Bilateral Angioma of the Retina.

Dr. A. HUGH THOMPSON showed a second Orbital Endothelioma occurring 11 years after removal of the first. He said he regarded it rather as a fresh growth than as a recurrence of the former one.

Mr. J. COLE MITCHELL showed three cases of Rodent Ulcer which had been successfully treated by means of carbon dioxide snow

Mr. N. BISHOP HARMAN showed a case with Dislocation of the Lens in the Posterior Chamber due to an accident 18 months before. The vision had remained excellent.

Mr. C. WRAY showed a new model of a Placido's Disc and Retinoscopic Lenses.

HARVEIAN SOCIETY OF LONDON.

Discussion on the Diagnosis and Treatment of Tuberculosis of the Urinary Tract.

A MEETING of this society was held on Oct. 26th, Mr. J. ERNEST LANE, the President, being in the chair.

Dr. SAMUEL WEST opened the discussion on the medical aspect, as already reported in THE LANCET of Nov. 11th, p. 1318.

Mr. HURRY FENWICK, in opening from the surgical side, said that pure urinary tuberculosis was of hæmic origin, descending and progressive, and rarely spontaneously cured. It started in a single kidney, the bladder was only affected secondarily, therefore the earlier the disease was attacked the greater was the chance of cure, and the bladder should be left alone to avoid implicating the sound kidney. He emphasised the importance of expert bacteriology, tubercle bacilli being rarely missed, and expert cystoscopy by which early B. coli cystitis and tuberculous cystitis could be distinguished. The ureteric orifice was the clue. Frequently the diseased kidney could be detected thereby. Radiography was rarely of value. He thought that the practitioner could discover 80 per cent. of the cases at the onset of symptoms of cystitis by reference to a bacteriologist. The cystoscopist could detect 45 per cent. of the cases, and frequently localised the kidney. He objected to the Luys separator and perferred the ureteric catheter, though even this involved risk, and the cystoscope was generally sufficient by itself. The death-rate from nephrectomy was from 2 to 4 per cent., and the relief was very great. He had used tuberculin for 18 years with great confidence, and good results, but he did not regard it as a cure. He thought that in many cases nephrectomy should be preceded by tuberculin. He advocated clean removal of the kidney without exploring the cortex, nicking the pelvis, or allowing any leakage from the cut ureter. He had contended for 20 years that washing out the bladder was dangerous from unavoidable risk of added infection. He advocated nephrectomy: (1) when the ureter was much thickened; (2) in advanced cases of unilateral tuberculosis; and (3) together with nephrostomy or ureterostomy on the opposite side in incurable cystitis. The bladder should only be operated upon in primary single tuberculous ulcer.

Captain S. R. DOUGLAS, I.M.S., said that his province of work involved the diagnosis of urinary tuberculosis by bacteriological methods and the treatment of the disease by a specific inoculation. Diagnosis was made by finding tubercle bacilli in the urinary deposit or by the inoculation of guinea-pigs with urinary sediment and subsequent examination. He gave technical details. He objected to inoculation of old tuberculin for diagnosis as being likely to cause a spread of the disease, to inhibit the excreting mechanism of the

kidney, or block the ureter by swelling. Von Pirquet's and Calmette's reactions only indicated the presence of tubercle and not necessarily urinary tubercle, and the same was true of observations on the opsonic index unless some interference with the urinary system, such as cystoscopic examination, induced fluctuation of the index. Treatment by tuberculin was markedly successful in urinary cases. In advanced cases improvement though marked was slow and the treatment must be long continued. Infection with other organisms added to the difficulty and required special vaccines. He mentioned the principles governing the administration of tuberculin and drew attention to the negative phase following inoculation and its importance in renal conditions. He advocated very small doses. The largest dose which he could find in records of 30 cases at St. Mary's Hospital was 1/4000th of a milligramme of bacillary emulsion and the smallest 1/400,000th of a milligramme. He advocated the use of the opsonic index for the regulation of the dose, but when that was impossible the following were clinical manifestations of a negative phase: (1) increased frequency of micturition; (2) increase of pain; (3) lassitude within a few hours of inoculation; and (4) rise of temperature. No dose should be increased which produced a satisfactory positive phase. Treatment should be continued for weeks or months after symptoms had disappeared.

Mr. W. H. CLAYTON-GREENE said that he felt assured of the rarity of primary tuberculous disease of the bladder. Tuberculous disease of the kidney was a primary lesion confined to one kidney only and amenable to complete extirpation. The tuberculous bladder should be left alone. He was convinced of the value of the use of tuberculin, the clinical symptoms being a sufficient guide to the size of the dose. He advocated large doses and had seen great improvement with 1/500th of a milligramme T.R.

Mr. J. W. THOMSON WALKER said that he should confine himself to the practical questions raised by Mr. Fenwick. The early detection of the disease meant diagnosis of tuberculosis of the kidney and of which kidney, that being the starting-point of the disease. The clinical symptoms were slight and misleading, even in advanced cases, and might be absent until fatal anuria set in. The symptoms when present were those of cystitis. There might be an enlarged and tender kidney, a source of difficulty in diagnosis, since it might be hypertrophied and active, the other being destroyed by tuberculosis. He quoted a case in which cystoscopy showed an active, inflamed ureter on the tender side and a blocked ureter on the opposite. The tender side might be affected, but to a less degree than the opposite. Examination of the urine usually enabled the diagnosis to be made, but not always, since the ureter might be closed. He quoted a case. Tubercle bacilli in the urine were not a certain sign of urinary tuberculosis in the absence of other signs, since the bacilli could be demonstrated in the urine in many cases of phthisis. A surgeon required to know if the kidney were affected and the condition of the second kidney. The cystoscope and the ureteric catheter were required. With regard to the use of this catheter the crux of the matter was: Was it possible to make a diagnosis of early renal tuberculosis by examining the orifice of the ureter? In early cases he thought this was not so, and that the ureteric catheter was, therefore, necessary in these cases. With regard to removal of the kidney, he urged immediate nephrectomy in unilateral tuberculosis, since the chances of spontaneous recovery were negligible. Among those who advocated waiting were those who recommended tuberculin. He had used this for eight years and had observed great improvement in symptoms in many cases, but very rarely a cure. The danger of waiting was that unilateral tuberculosis might become bilateral. When cases were first met with 14 to 20 per cent. were bilateral, in late stages 55 per cent. were bilateral. The mortality in operations was 2·8 per cent., and in 230 cases there had been no death from tuberculosis within two years of nephrectomy. There was no means of telling when infection of the second kidney was about to take place, he therefore urged operative treatment in unilateral tuberculosis, and he advocated tuberculin in early unilateral tuberculosis when nephrectomy was refused, in bilateral tuberculosis, in vesical tuberculosis, after nephrectomy, and in the combination of renal and extra-urinary tuberculosis.

Dr. WEST, Mr. FENWICK, and Captain DOUGLAS replied.

MANCHESTER MEDICAL SOCIETY.

Auricular Fibrillation.—Headache in Children.—Salvarsan.

A MEETING of this society was held on Nov. 1st, Dr. A. M. EDGE being in the chair.

Dr. C. E. LEA communicated a paper on Auricular Fibrillation, in which he said: The degree of practical importance of the arrhythmia associated with the fibrillary tremor of the auricle is proportionate to the amount of strain thrown upon the cardiac musculature by its incidence. The arrhythmia of auricular fibrillation is characterised by the continuous irregularity of the ventricular rhythm, the absence of auricular contraction, and the dilatation which, if the arrhythmia is long continued, occurs. In animals auricular fibrillation can be produced by (1) direct faradic stimulation of the auricle, (2) toxic doses of digitalis, and (3) in some cases by stimulation of the vagus. In man fibrillation has not been observed in the absence of some pre-existing cardiac lesion. Most lesions may lead to fibrillation, not only those associated with gross muscular change, but also in cases where the rhythm is markedly disturbed. Cases of the latter are exemplified by the fibrillation which, in some cases, follows directly upon paroxysmal tachycardia. A case is reported by the writer in which it succeeded heart-block. The exciting causes of fibrillation are variable. It is sudden in its onset and offset. The ventricular frequency induced by fibrillation is variable. It may be associated with very rapid frequency; moderate, as in many cases of cardio-sclerosis; or with bradycardia. The pathology of the latter class is obscure. The degree of cardiac dilatation is greatest where there is a rapid frequency. No method of treatment has, so far, been found to check the fibrillation. Digitalis acts beneficially because it probably induces lessened *a.-v.* conductivity, and so diminishes the number of supra-ventricular or auricular impulses. Auricular fibrillation may be associated with complete heart-block. The diagnosis of auricular fibrillation was discussed, and its significance emphasised.

Dr. HUGH T. ASHBY read a paper on Headache in Children. He said: There is probably no symptom of ill-health more commonly met with than headache, and it is on account of its being so common and at the same time so obscure in its origin in some cases that the subject is of real importance. A complaint of headache in a child should always receive attention, especially if it is at all repeatedly complained of. Headache is not easily recognisable until about the age of 4 to 5 years, but it is quite certain that infants and young children do suffer from headache by the way they will bang and beat their heads—e.g., in ear disease. The locality of a headache is not of much importance except in a few instances like the ocular headaches, which are nearly always frontal. Headache is an almost constant, and certainly the most frequent, symptom of cerebral tumour and meningitis, and in 16 cases of cerebral tumour in children 15 had severe headache. The one case without headache was a tumour of the pons, where there was also no optic neuritis. The neurotic headache is a very distinct type; it occurs frequently in girls over 10 years of age, and it is very difficult to treat. Decayed teeth predispose to ill-health, and in this way make a headache more liable to be noticed, but they do not in themselves often cause a headache in children. Anæmia is nearly always accompanied by headache and is due to a lowering of the blood pressure, together with the poor quality of the blood.

Dr. G. H. LANCASHIRE read a paper on Salvarsan, giving the result of intra-muscular injections in a series of 28 selected cases, including primary, secondary, and tertiary stages of syphilis. The results had been good except in the last case tried, a severe tertiary case which showed no improvement. He had observed no untoward symptoms, either general or local. He regarded salvarsan as a valuable aid, used in conjunction with mercury, in certain cases of syphilis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on Nov. 10th, Dr. A. Bostock Hill, the President, being in the chair.—In introducing a discussion on the National Insurance Bill Dr. H. Meredith Richards confined his remarks entirely to the public health aspects of the measure. The purpose of the

Bill was to provide material aid in time of sickness and to prevent and cure disease. The latter object, he considered, was in the main the more important. In practice it was probable that the immediate effect of the insurance scheme on preventive medicine would be proportional to the initial bias of the Insurance Committees and to the extent to which their work was harmoniously coördinated with existing public health organisations. In most districts it would be an advantage if the chairman of the public health committee and hospital committee of the county or borough councils and the chairman of the education committee were nominated to represent the county or borough councils. Referring to the provision in the Bill which requires reports and returns as to sickness, &c., to be made by the Insurance Committee to the Insurance Commissioners, he expressed the opinion that this most important duty would require much expert knowledge and administrative skill if the central and local authorities were to have the information in a form which they could assimilate and use for practical ends. He suggested that the sickness returns should be furnished to the medical officer of health at weekly or monthly intervals, and that it should be made obligatory on him to report upon the returns to the Commissioners, the Local Government Board, and to the local sanitary authority concerned. The proposed extension of the sanatorium benefits to the dependents of insured persons would give an immense impetus to the provision of sanatoriums and to other specialised methods both for detecting and for treating phthisis. The relation of the pre-tuberculous school child to the phthisical adult; the importance of securing early treatment for adenoids and enlarged tonsils which were often the portal selected by the tubercle bacillus; the relation of dental defects to malnutrition and of malnutrition to phthisis—these would become very practical problems when the comprehensive treatment of phthisis was actually undertaken.—Dr. E. W. Hope was convinced that the Bill would give facilities for the advancement of preventive medicine in the future. He agreed that it would be a distinct advantage to have on the Local Insurance Committees the chairmen of the health and education committees. He considered that a large amount of the information which the Insurance Committees were empowered to obtain was already in the hands of medical officers of health.—Mr. F. E. Fremantle spoke in approving terms of the alteration of the name of the Local Health Committee to that of Insurance Committee. He doubted very much whether it would be practicable to put in force the penalising clauses with respect to excessive sickness.—Dr. E. H. Snell pointed out that there was no provision in the Bill for putting official information at the disposal of the Insurance Committee. He feared there would be too many overlapping authorities.—Dr. R. Dudfield spoke in general approval of the Bill, but regretted there was no reference in it to the metropolis as such. He thought that the penalising clause (46) should have been postponed for five years.—Dr. W. Butler deplored the fact that under the Bill there would be a supersession of existing public health authorities. He considered it would be utterly impossible to bring home to sanitary authorities the fact of maladministration.—Surgeon-General G. J. H. Evatt considered that medical men would have to be much better trained than at present if they had to give reports on sickness. Those in general practice would be compelled to go through a post-graduate training.—Mr. Herbert Jones anticipated that Clause 46 would have a good effect in stimulating rural authorities into more activity.—The President agreed that rural districts were most largely affected by the clause, and he pointed out that before any penalty could be enforced an inquiry would have to be made by a competent person, who, in his opinion, ought to be a medical man.—Mr. J. G. Gibbon, Dr. A. Ashkenny, Dr. J. Howard-Jones, Mr. C. Randle Harper, Dr. W. A. Bond, and Mr. Montague Harris also took part in the discussion.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 3rd, Dr. John Brownlee, Vice-President, being in the chair.—Dr. David Newman reported a small series of cured cases of Primary Vesical Tuberculosis, and discussed the questions of early diagnosis, prevention, and treatment of primary and secondary tuberculosis of the bladder, illustrating the cystoscopic appearances by the opaque projector. He said that for practical purposes the disease might be divided into five stages: (1) The stage when tubercle bacilli were present in the urine prior to obvious infection of the bladder; (2) stage of isolated submucous nodules; (3) stage of tuberculous infiltration prior to ulceration and erosion; (4) stage of superficial ulceration; and (5) stage of widespread infiltration of the surrounding structures and deep ulceration of the bladder. Two cases of early vesical tuberculosis, one operated on lately, another treated five years ago by curetting the bladder, were described. The latter has been in perfect health and the urine free from tubercle bacilli since the operation. Other two cases, one man operated on in February, 1911, the other operated on in February, 1904, were cited as complete cures, all the symptoms having disappeared and tubercle bacilli being absent from the urine. The treatment employed was suprapubic drainage and curetting the tuberculous area, together with the employment of tuberculin R. and general constitutional treatment. The relationship of tuberculous cystitis to renal, prostatic, and testicular tuberculosis was discussed, and statistics of 25 cases treated during the last seven years were given.—Dr. John Guy gave an account of his experience in the treatment of pulmonary tuberculosis by means of tuberculin in the sanatorium at Bridge-of-Weir. He had treated recently a series of 75 cases, and stated the results of treatment in 41 of these who had been under treatment for periods varying from four to 11 months, showing the effects of the remedy on the sputum, the tubercle bacilli and the lung condition. The tuberculin was given by subcutaneous injection in doses beginning with 0·001 milligramme and gradually increasing to the equivalent of 10 milligrammes of tubercle bacilli. In many cases doses much smaller than 10 milligrammes produced a febrile reaction and could not be exceeded. The estimation of the opsonic index was found to be of no practical use in tuberculin treatment. The conclusion reached was that tuberculin could be administered with comparative safety if the dosage were carefully regulated and the temperature watched; that from a clinical standpoint one variety of tuberculin appeared as good as another, but that the bacillary emulsion sometimes caused unexpected reactions. A comparison between the results obtained by the tuberculin treatment of these 41 patient and those obtained in the treatment without tuberculin of an equal number of patients in similar stages of the disease seemed to show a balance in favour of tuberculin, though the number of cases was too small to warrant a definite conclusion.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — A meeting of this society was held on Nov. 8th, Mr. C. A. Morton, the President, being in the chair.—Dr. J. R. Charles showed a boy aged 6, the subject of Myatonia (Amyotonia) Congenita, and read a paper on the disease.—Dr. J. M. Fortescue-Brickdale discussed the two types of this disease, in one of which changes in the anterior horn cells were found constituting a spinal paralysis, while in the other only muscular lesions existed—a true myopathy.—Dr. F. Carey Coombs referred to a case he had described five years ago, the first reported in the United Kingdom. In that case the trunk muscles had suffered more than the limbs, whereas in Dr. Charles's case the peripheral muscles were chiefly affected. In the case under Dr. Coombs the face muscles were affected in the late stages of the disease. He was not sure whether amyotonia congenita was a true myopathy. Myopathies were always progressive, whereas arrest of the wasting and even improvement might occur in this disease.—Dr. A. L. Flemming showed: 1. A case (an adult woman) in which Filaria Loa had been Removed from the Subconjunctival Tissue of the Orbit. The disease had previously been diagnosed from the presence of an abscess in the back which proved to be a "Calabar swelling," a marked eosinophilia, and the discovery of diurnal filaria in the blood. 2. A case of a Rapidly Growing Endothelioma of the Cheek, which recurred after erosion in both the scars and pre-auricular gland, treated by radium with apparently complete disappearance of the growth. 3. A young woman in whom an Adrenal Adenoma of the Liver had been removed by laparotomy. Her symptoms had been sudden amenorrhœa, headache, lassitude, increasing bronzing, growth of hair on the face and loss of scalp hair, and marked unsociability. Deep jaundice suddenly developed with colic; at the operation two nodules were found on the liver, one of which was compressing the common duct. Microscopically they had the structure of adrenal adenoma. A similar case had been reported in the *British Medical*

Journal, Sept. 2nd, 1911, Epitome, p. 35.—Dr. Watson Williams read a paper on Cardio-vascular Nasal Reflexes and their Clinical Import.—Dr. Newman Neild read a paper on Tea-poisoning, in which he described a series of clinical signs and symptoms which in his opinion were characteristic of, and peculiar to, chronic excessive tea-drinking. He claimed for tea-poisoning a distinct and definite entity.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Nov. 2nd, Mr. T. H. Ionides, the President, being in the chair.—Dr. F. Hinds showed a mass of Lymphadenomatous Glands removed from the right side of the neck of a female aged 23. The glands were extremely adherent to the surrounding parts, and the sterno-mastoid was thinned out over its surface and partly removed with it. On section the mass was very firm and fibrous, and in the centre were patches of broken-down caseating material. The enlargement of the glands had existed for more than four years, and was on both sides of the neck and in the axillæ. The spleen within the last six weeks had become palpable, though only to a small extent. The patient had no anæmia or other symptoms of ill-health. The growth was removed on account of the deformity which it produced, being as large as a cocoa-nut, and also because the skin over it was getting red and œdematous. A blood examination showed some excess of white corpuscles and eosinophiles. There was no pyrexia. Recovery from the operation was uneventful. Microscopic specimens showed the structure of lymphadenoma. The indurated and caseating condition is very unusual and gave to the specimen the appearance of tubercle.—Dr. R. J. Ryle showed a boy and his two sisters all suffering from Bilateral Congenital Cataract. He was treating them by needling and hoped to give them useful vision.—Mr. H. H. Taylor showed, for Dr. J. R. Steinhaeuser, a case of Sarcoma of the Choroid in a man about 50 years of age. The ophthalmoscope revealed a detachment of the retina at the lower and outer part of the field, which Mr. Taylor thought was caused by a growth behind it.—The President delivered the annual address and selected as his subject Uterine Fibroids. He described their frequency, classification, symptoms, diagnosis, prognosis, and treatment. He considered that hysterectomy was in the majority of instances the proper operation, the mortality of which should not be above 3 per cent. in all cases. As regards after-treatment, he advocated Fowler's position, early movement of the bowels, hot saline injections, and avoidance of starvation. The period of convalescence was much longer than was usually given.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Nov. 8th.—Dr. Ralph Vincent (London) read a short paper on the Development of Acidity in Milk and its Relation to Time and Temperature. This was based upon a series of recent observations and experiments in the research laboratory of the Vincent-square Infants' Hospital, London, and demonstrated the constancy of the influence of both the length of time and the variation of the temperature to which milk is exposed in increasing its acidity. As commercial milk even of good quality was contrasted with the milk brought from the hospital farm to the advantage of the latter, this paper carried its own practical lesson as to the precautions necessary for a pure milk-supply in the prevention of bacterial contamination, the chilling and keeping of the milk cool, and the rapidity of transit to the consumer.—Dr. Vincent then delivered an address on the Substitute Feeding of Infants, and gave a detailed account of the principles and practice of milk modification for this purpose. He began by contrasting the state of matters 100 years ago and now as to maternal nursing, and blamed the modern education and increasing stress and rush and mental strain imposed on women for the gradual failure of lactation. A study of the work of Dr. Rotch in America has helped him in the development of the methods of milk modification which have now been elaborated in the present Infants' Hospital and the associated hospital farm and well-equipped laboratory. Lantern slides illustrating all these places were shown, and their methods of cooling and keeping cool the milk, and of separating its elements for fresh combinations according to the special prescription of the physician. Dr. Vincent concluded by describing cases, throwing on the screen a copy of the diet chart showing the variations in the modification of the milk prescribed and of the weight chart. Among the cases described were congenital syphilis, congenital defect, pyloric stenosis, atrophy, fat intoxication, and rickets. In concluding he recommended the study of biological chemistry as likely to yield the best results in the future.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Nov. 3rd, Mr. F. Lace being in the chair.—Dr. Rupert Waterhouse showed a woman, aged 37 years, suffering from Splenic Anæmia. She was mother of five children; each of her pregnancies had been complicated by "dropsy." After the last confinement, three years ago, her abdomen again swelled, and when seven gallons of fluid had been removed by tapping the enlarged spleen was detected. The edge of the liver was just palpable and the blood showed—erythrocytes, 3,000,000 per c.mm.; hæmoglobin, 30 per cent.; leucocytes, 1500 per c.mm. A few normoblasts were present, but the differential count of leucocytes was normal.—Dr. James Lindsay showed a man, aged 55 years, suffering from Multiple Neuro-fibromata; the original appearance of the disease was 30 years ago.—Dr. V. Wiley showed a large specimen of an Innominate Aneurysm removed from a woman, aged 59 years; the ascending aorta showed another dilatation and the thoracic aorta a fusiform aneurysm.—Mr. A. L. Fuller read notes of two cases of Carcinoma of the Small Intestine. One case was that of a woman, aged 55 years, who had suffered from mucous colitis for three years, and who developed symptoms of obstruction. An annular carcinomatous stricture of the upper part of the ileum together with 3 feet of the small intestine and mesentery were removed, and end-to-end anastomosis was performed. Rapid improvement in health and weight took place with no further return of the colitis. Death occurred 4½ years later from recurrence. The second case was that of a woman, aged 38 years, who had a Carcinomatous Stricture of the Middle of the Transverse Colon. Owing to the mesentery being full of growth, removal was impossible, so lateral anastomosis was performed. A year later, when operating to relieve further obstruction, multiple carcinomatous strictures of the small intestine were found; lateral anastomosis to relieve urgent symptoms was again performed. The patient died six months later.

Reviews and Notices of Books.

A Practical Handbook on Diseases of the Ear, for Senior Students and Practitioners. By WILLIAM MILLIGAN, M.D. Aberd., Aurist and Laryngologist to the Royal Infirmary, Manchester; Surgeon to the Manchester Ear Hospital; Lecturer upon Diseases of the Ear to the Victoria University of Manchester; President of the Otological Section of the Royal Society of Medicine; and WYATT WINGRAVE, M.D. Durh., Pathologist (late Physician) to the Central Throat and Ear Hospital, London, and to the Polyclinic, London. With 293 illustrations and 6 coloured Plates. London: Macmillan and Co., Limited. 1911. Pp. 596. Price 15*s.* net.

THE first two chapters, which are brief, deal with the development of the ear and the anatomy of the external ear; the third gives a short *résumé* of the physiology of the ear. The fourth chapter deals briefly with the causation of aural disease, whilst that following, of rather over 40 pages, gives detailed instruction as to the examination of the ear, nose, naso-pharynx, and pharynx, with numerous illustrations of the appropriate instruments, and including the methods of the tests for hearing. The tuning forks recommended are those of Hartmann. The description of the various tests is clear and concise, not going too deeply into the theory of sound, which is beyond the average medical student or medical man. A useful piece of information, which is not given in many works at present, is the formula recommended for use in testing deaf people at the last Otological Congress in 1909. The authors give very careful directions as to the use of the Weber-Liel intra-tympanic tube as a

means of passing fluid into the middle-ear, and of Hay's pharyngoscope, of which the use is advocated.

Deformities of the external ear, followed by injuries of the auricle and external auditory meatus, form the subject of the next two chapters. Chapter VIII., on diseases of the auricle, is well illustrated by figures of sections of various new growths, and also contains lucid descriptions of diseases affecting the auricle, with their appropriate treatment. Foreign bodies in the ear and diseases of the external auditory meatus occupy the next two chapters. One of the plates shows three forms of parasite occasionally found growing in the ear. This illustration is extremely well executed.

The anatomy of the middle-ear is fully described and illustrated in Chapter XI. Catarrhal otitis media in its acute and chronic forms, with their complications and sequelæ, is ably dealt with in the fourteenth and fifteenth chapters. Acute and chronic suppurative otitis media and the appropriate treatment occupy the succeeding two chapters. In Chapter XIX. one finds a mine of information in reference to the Bacteriological Examination of Discharges. This is a branch of the subject with which both the writers' names are intimately associated, and not only does the account contain all the information that has gradually been made known, but, coming as it does from the source of the information itself, it is particularly valuable and interesting. Aural polypi, cholesteatoma, and tuberculous diseases of the middle ear form the subjects of the next two chapters. Of these, the last has been associated with the name of Dr. Milligan as one of its earliest and most earnest investigators, for many years.

In Chapter XX. disease of the mastoid process with all its accompanying sequelæ, and the proper methods of dealing therewith, are carefully and clearly enumerated. Tinnitus, its differential diagnosis and treatment, forms the subject matter of Chapter XXVIII. The next three chapters are devoted to intracranial lesions secondary to aural diseases, both the text and the illustrations being extremely clear, and the descriptions, especially of the operations, leaving nothing to be desired.

The thirty-second chapter deals with the anatomy of the internal ear. Disease of the labyrinth is dealt with in Chapter XXXIII., and all that is known at present on this matter is given. Oto-sclerosis is ably dealt with in a subsequent chapter, which is followed by one on inflammatory diseases of the labyrinth. Amongst the later interesting chapters one finds references to diseases of the ear in relation to general medicine, deaf-mutism, and aural disease and life insurance, while diseases of the nose, naso-pharynx, and pharynx, especially liable to involve the organ of hearing, fittingly occupy the concluding chapters.

This book is one the perusal of which has proved a source of great pleasure. Although it is no small work, yet there is nothing we would wish omitted, and we have not discovered the omission of anything which should have been included. The diction is easy and the descriptions are plain; the illustrations are excellent and the printing is good. Dr. Milligan and Dr. Wingrave have given us the most comprehensive work on diseases of the ear which has been published in the British Isles, and it is one which, although professedly for senior students and practitioners, will doubtless be found equally welcome by those who deal more especially with aural surgery. It is extremeley gratifying that the authors have been able to quote so freely from the work of their British colleagues, while they themselves give a practical demonstration of the progress of British otology.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLIII., Nos. 1 and 2. Cambridge University Press: C. F. Clay. Sept. 11th and Oct. 20th, 1911. Price 6*s.* 6*d.* and 7*s.*—The first paper, by Harriette Chick and C. J. Martin, on Heat Coagulation of Proteins, is a continuation of a previous paper (*Journal of Physiology*, vol. xl., 1910). "Heat coagulation" of egg-albumin consists of two processes: (1) the reaction between the protein and hot water ("denaturation"), and (2) the separation of the altered protein in a particulate form (agglutination). The rate of (2) was arranged to be greatly in excess of that of (1) in the experiments, so that (1) is the limiting factor in the process. During the process, as protein is precipitated, free acid is progressively removed from the solution. The extra amount of acid fixed by egg-albumin in coagulation was determined and its cause explained. The coagulate rate is lowered by the presence of salts, e.g., NaCl and Am_2SO_4. The short paper by F. O'B. Ellison, The Relation between the Physical, Chemical, and Electrical Properties of the Nerves, Part V., The Action of Cinchonamine Hydrochloride on Frog's Nerve, is the fifth of the series, and is chiefly interesting to physiologists, as it deals with the specifically different action of cinchonamine hydrochloride on the injury current and on the negative variation of frog's nerve. Arthur Harden and Hugh Maclean's paper on the Oxidation of Isolated Animal Tissues is a continuation of a previous paper on that abstruse question. Minced organs and tissues of animals have no more power of producing carbonic dioxide from sugar when incubated in an atmosphere of oxygen than they have in an atmosphere of nitrogen or hydrogen. Tissue juices obtained either by the kieselguhr, the aqueous, or the saline method possess little or no respiratory action. Antiseptics and grinding the tissues with sand materially lower the oxidation processes.

The long communication, over 40 pages, of Keith Lucas on the Transference of the Propagated Disturbance from Nerve to Muscle, with special reference to the apparent inhibition described by Wedensky, is an elaborate investigation of the Wedensky effect (1885)—i.e., the "apparent inhibition" observed in a muscle excited from its motor nerve. The author's endeavour is to show that this effect depends for its possibility on a simple property known to be possessed in high degree by the synapse of the central nervous system—namely, a resistance to conduction greater than that of the continuous axon. The paper is especially interesting to physiologists. In a short paper on the Effect of Stimulation of the Eighth and Ninth Spinal Nerve-roots upon the Bladder of the Toad, Frank P. Knowlton finds that the arrangement of the autonomic system in the toad is similar to that of the frog; that stimulation of the eighth nerve-root produces no effect on the bladder. No evidence of efferent fibres in the posterior roots was found. H. M. Vernon gives an account of his further investigations on the Indophenol Oxidase of Mammalian and Avian Tissues. He finds it to be most abundant in the heart muscle, whilst the liver, with one exception, is poorest. The amount of oxidase in various tissues of the rabbit, cat, and dog roughly corresponds with their degree of oxygen saturation, as determined by Ehrlich by his *intra vitam* staining methods. In birds there is a close parallel between the oxidasic power of the tissues and the respiratory exchange. The canary has eight times the CO_2 output of the goose. The oxidasic power of a tissue depends largely on its power of sustained activity—e.g., the pectoral muscle in vigorous flying birds is as rich in oxidase as the heart, and three times as rich as limb muscle, while in the tame duck pectoral muscle contains scarcely any

oxidase. In mammals red muscles contain much more oxidase than white, and tongue and diaphragm most of all next to the heart. Cold-blooded animals have very little, while in small embryos it is at a minimum, and rapidly increases with embryonic development, and for the first fortnight of post-natal existence. The liver for a week or two after birth is richer in oxidase than the adult liver.

In Vol. XLIII., No. 2, the paper of Mutch and Pembrey on the Influences of Tetrahydro-B-Naphthaline upon the Temperature and Respiratory Change deals chiefly with the relation of the rise of temperature to muscular activity. The drug, the action of which was first investigated by Stern, causes extreme dilatation of the pupil, constriction of the vessels of the ear, rapid respiration, restlessness, greatly increased muscular activity, spasms, and even convulsions. In fatal cases death may be due to either hyperthermia, paralysis, or cyanosis with cardiac failure. The increased heat appears to bear a definite relation to the muscular activity, and is accompanied by an adequate increase in the intake of oxygen and the output of carbon dioxide. The action of the drug is upon the central nervous system, upon the higher more than the lower, the increased excitability being accompanied by increased muscular movement, spasms, and even convulsions. The rise of temperature, at any rate in the non-fatal cases, can be explained by the increased muscular activity. Convulsions were present in each case when death occurred from hyperthermia, a condition favoured by the cyanosis present. The processes of oxidation and heat production are increased when the temperature of an animal is raised above its optimum, so that it is unnecessary to expect a persistence of vigorous muscular movements during the whole time the temperature is rising. There is a marked antagonism between the drug and anæsthetics; in suitable doses it prevents chloral narcosis, and chloral or chloroform will arrest the rise of temperature produced by the drug.

Professor Langley's paper on the Effect of Various Poisons upon the Response to Nervous Stimuli, chiefly in Relation to the Bladder, is the largest contribution. The experiments were made on anæsthetised cats. Starting from his own observations on the antagonistic action of curari and nicotine upon peripheral nerve cells, the author discusses the nature of that action. The nerves to the bladder were exposed—the bladder itself being previously filled with a mixture of normal urine and warm salt solution, so that the bladder could contract under nearly isotonic conditions. The sacral nerves were stimulated in pairs; the alkaloids were injected into a vein and faradic stimuli were increased. Numerous tracings are given to show the effects or responses obtained. Stimulation of the sacral autonomic fibres affects nerve fibres, nerve cells, and the smooth muscle of the bladder. The author concludes that it is the nerve cells which are affected by the drug. Stimulation of the sacral nerves, which contain vesico-motor fibres, caused strong contraction of the bladder, as shown by the curves taken of variations of the internal volume of the bladder. If the stimulus is brief relaxation soon sets in; if the stimulus is prolonged relaxation sets in more slowly. No clear evidence was obtained of the presence of inhibitory fibres in the normal condition. After injection of nicotine the first effect of stimulating the sacral nerve is inhibition. Nicotine stimulates the peripheral nerve cells. There is antagonism between nicotine and curari and both act on the peripheral nerve cells. When curari or nicotine has been injected stimulation of any branch of the pelvic plexus, which has pre-ganglionic fibres, causes after-contraction, but stimulation of post-ganglionic fibres on the bladder causes a normal contraction with no after-contraction. We must refer to the original paper for the remarks of the author, more especially when he himself says: "I do not think any final conclusions can be drawn as to the cause of the various phenomena described in the paper." The paper of H. H. Dale and P. P. Laidlaw (Wellcome Research Laboratory) on the Action of Iminazolylethylamine is a continuation of a previous paper (*Journal of Physiology*, vol. xli., 1910). The drug causes a vaso-dilator fall of blood pressure in carnivora and in the monkey and fowl, and this is due to a direct action of the base and not to the liberation of a vaso-dilator substance in the body. It is independent of the integrity of the peripheral sympathetic neurons, but is not due to direct action on the smooth muscle. It also causes a large and rapid fall of rectal temperature. The note by the same authors on reversed action of the chorda tympani on salivary secretion is interesting. Under certain conditions—after nicotine, curari, hordenine, tropine—a reversed action of the vagus is possible—i.e., the cat's heart may be accelerated during, and inhibited between the periods of, stimulation. On using cytisine, the alkaloid of laburnum seeds, the authors obtained a secreto-inhibitory action, instead of the usual excito-secretory effect.

In the short paper communicated by the late Dr. F. W. Pavy and W. Godden on Some Recently Elicited Facts Relating to Carbohydrate Metabolism and Glycosuria, experiments are given to support Pavy's contention that sugar is taken from view by the incorporating agency of bioplasm, what is not so dealt with being discharged from the system with the urine. The paper by T. Graham Brown and C. S. Sherrington—Observations on the Localisation in the Motor Cortex of the Baboon (Papio anubis)—is illustrated with elaborate charts of the cerebral motor areas. The localisation in the motor cortex of the baboon agrees closely with that found in other simian types examined. As regards specialisation, it lies between macacus and the anthropoid types. On the pre-central gyrus from below up the successive areas are for lower face, upper face, neck, arm, chest, abdomen, leg, and perineum. Face movements are particularly clearly demonstrated. Overlapping of individual representatives in each of these main areas is very marked. The following are some of the titles in the Proceedings of the Physiological Society for July 22nd, 1911:—P. G. Ward: The Study of the Action of Various Salts on Isolated Muscle; I., Sodium, Potassium, and Ammonium Salts. B. R. Macmillan: A New Form of Perfusion Stopcock. Casimir Funk: Note on the Probable Formation of Adrenaline in the Animal Body. L. Bull: On the Simultaneous Record of the Phono- and Electro-cardiogram. F. W. Edridge-Green: Lantern for the Quantitative Estimation of Defects of Colour Perception.

The Archives of the Roentgen Ray under the energetic editorship of Mr. W. Deane Butcher is a most valuable periodical. The outstanding feature of the October number is that of the X ray treatment of malignant disease. The point of view taken by Professor S. Leduc, of Nantes, is one that has much to recommend it, and should be widely read. Dr. Reginald Morton treats the same subject in a very temperate spirit; he makes a plea for the more general use of post-operative attention, and points out the feasibility of treating the operation area before the wound is closed. The plates in this number are taken from some made in the General Hospital of Birmingham by Mr. J. Hall-Edwards and Mr. F. Emrys-Jones. Those showing disease and injury about the skull are very fine.—The November number, just issued, is also of unusual interest, and contains articles contributed from France, Germany, and Austria. Professor Leduc's article on Molecular Physics contains some interesting studies on the phenomena of solution, in continuance of his fascinating investigations on osmotic growth,

which excited so much interest at the Royal and other learned societies last winter. Professor Albers Schonberg contributes an article on the new Lindeman focus tube, of lithium glass, which promises to be a great advance in X ray tube construction. The most interesting paper, however, is that by Dr. Guido Holzknecht on the Roentgen Diagnosis of the Stomach. This is admirably illustrated and contains very definite and practical suggestions for the diagnosis of gastric diseases, as well as a description of Haudek's simplified method for the Roentgen examination of the stomach by means of a double bismuth meal. The "Notes and Abstracts" found in each issue are judiciously selected to form a guide to the current literature dealing with the subjects of the journal itself. The change in size and arrangement of the "Archives," on which we commented about a year ago, has rendered this journal much more handy and convenient.

The Medical Chronicle.—In the October issue is published a thesis by Dr. P. Moran on the Pharmacological Action of Tincture of Digitalis, with special reference to the mode of its preparation and to the effects of age. He concludes that the drug deteriorates with keeping; possibly the digitoxin is decomposed. But a reliable preparation made with 90 per cent. alcohol should remain useful for two or three years. A second thesis, by Dr. Herbert Tomlin, deals with miners' nystagmus, which the author attributes to the rhythmical swaying action of using a pickaxe, aided by the bad illumination and by the optical effects of the crystalline fracture of the coal.

Edinburgh Medical Journal.—A paper by Dr. A. Logan Turner on the Spread of Bacterial Infections from the Nasal and Naso-pharyngeal Cavities by Way of the Lymphatic Channels appears in the November number of this magazine. The author considers that the assumption of a flow of lymph from the nose to the brain is improbable, the current, if any, being presumably in the opposite direction. On the other hand, tubercular infection may be conveyed from the nose to the cervical lymphatic system. Dr. G. Duncan Whyte discusses the causes of the prevalence of pulmonary tuberculosis in South-east China, and Dr. James Oliver writes on Utero-sclerosis and Sclerosis of the Recto-utero-vesical Fascia.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

(1) ALCOHOLIC EXTRACT OF GUINEA-PIG'S HEART; (2) HÆMOLYTIC SERUM FOR SHEEP'S CORPUSCLES; AND (3) EPININE FOR OPHTHALMIC USE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

1. THE alcoholic extract of guinea-pig's heart is for use as an antigen in the Wassermann reaction, replacing the extract of syphilitic fœtal liver originally used by Wassermann. It is an obviously convenient preparation for the modern diagnosis of syphilis, and is obtained by digesting the finely minced hearts in alcohol and, finally, filtering the fluid. 2. The hæmolytic serum for sheep's corpuscles is prepared by inoculating an animal with sheep's red corpuscles. Ultimately the serum of the inoculated animal acquires the property of hæmolysing sheep's corpuscles. As a dilution it can thus be used as a hæmolytic serum in the Wassermann and other complement deviation tests. 3. Epinine, the synthetic substance having a pharmaceutical action similar to that of the suprarenal active principle, is now prepared in tabloid form for ophthalmic use. Each tabloid contains 0·006 gramme of epinine. In this form this valuable hæmostatic can be easily applied to the eye.

VITTEL WATER (GRANDE SOURCE).

(E. DEL MAR, 12, MARK-LANE, LONDON, E.C.)

Vittel water has enjoyed a reputation in the treatment of gout and kidney troubles. It affords the centre of attraction to the health resort Vittel, an interesting old town situated to the south-east of Paris and about 70 kilometres from the German frontier. Recently Vittel has developed considerably and a new colony has sprung up about half a mile from the old town, where hotels and the usual appurtenances of a health resort have been erected in view of increasing demands. The environment of New Vittel is attractive and there are facilities for open-air recreations. The waters appear to be most beneficial in the treatment of gout and allied disorders, but, like so many other waters, a mere chemical analysis does not seem to supply an explanation of the practical good obtained by their use. According to our analysis, Vittel water from the Grande Source contains about 1·836 grammes per litre of mineral salts, and the principal constituents are the sulphates of lime, magnesia, and soda in approximately equal quantities. Generally speaking, a water that contains sulphates shows radio-activity, and this may have something to do with the valuable medicinal properties of Vittel water. Then, of course, a strict *régime* of a course of water is an advantage in many of the cases which treatment at Vittel benefits. The water is, further, alkaline by reason of the carbonates of the alkaline earths present. Apart from the value of the waters in the treatment of disease, there are provided at Vittel all the essentials of hydro-therapeutic practice.

PEPTO-MANGAN (GUDE).

(AGENCY, THOS. CHRISTY AND CO., 4-12, OLD SWAN-LANE, LONDON, E.C.)

The important ingredients of this preparation are, according to our analysis, iron and manganese, both of which are in organic combination. The addition of ammonia produces no precipitate, but the addition of caustic soda does. The presence of peptones was confirmed, and the inference is that iron and manganese occur as peptonates, an admittedly useful form of administering these metals where a hæmatinic is indicated (chlorosis, anæmia). There is present also ammonia, for on heating with soda a strong smell of ammonia was evolved. The same result is obtained when the ammonium citrate of these metals is similarly treated. The preparation is a clear brown fluid and palatable. According to some clinical reports which have been submitted to us its administration distinctly effects an increase in the number of red corpuscles and in the amount of hæmoglobin. Our analysis gave the following figures:—Alcohol by volume, 18·25 per cent.; total solid matters, 4·39 per cent.; mineral matter, 0·83 per cent., containing 0·44 of ferric oxide (Fe_2O_3) and 0·13 per cent. of manganic oxide (Mn_2O_3).

ORIENTAL TOOTH PASTE.

(JEWSBURY AND BROWN, ARDWICK GREEN, MANCHESTER.)

This tooth paste satisfies the requirements of an application intended to keep the teeth scientifically clean. It contains a polishing agent, an antacid substance, and agreeable antiseptics chiefly in the form of aromatics. It is quite pleasant to use, is free from grittiness, and leaves a pleasant impression in the mouth. Further, it has mild astringent properties.

MARVIS FLAKES.

(MARVIS AND CO., 4, STARR-YARD, CAREY-STREET, LONDON, W.C.)

We have examined this food preparation previously, but recently a further improvement has been made, inasmuch as the flakes are now prepared from fresh instead of salted fish. The flakes are clean and white and contain all that is

nourishing in the fish itself. They are free from diagreeable odour or taste. According to our examination starch is an important adjunct in the drying process. We found just over 50 per cent. of proteins present. The flakes are a cheap source of protein food and, when cooked properly, can be made the foundation of an appetising dish.

FORMITROL.

(A. WANDER, LIMITED, 1 AND 3, LEONARD-STREET, LONDON, E.C.)

These formalin pastilles show evidence of improvement on their former production. The active constituent is formaldehyde, with which are associated menthol, citric acid, and milk sugar for convenience of administration. The tablet is firm and is grooved with lines which enable it to be broken into definite fractions, which is convenient in cases when smaller doses are required. The pastilles are designed for the bactericidal treatment of the throat. Each individual tablet is wrapped in tin-foil, which tends to preserve the standard strength of the pastille as regards formaldehyde.

APONAL.

(WIDENMANN, BROICHER AND CO., 33, LIME-STREET, LONDON, E.C.)

Several synthetic hypnotics have fallen out of favour of recent years owing to the fatalities which have resulted from their use. There has been uncertainty in regard to their action, and on the whole it would appear that some of them possess an action in some cases which is too intense for the purpose. Aponal is regarded as a mild hypnotic which is useful in the treatment of insomnia and which, so far as the clinical evidences of its use have gone, is without undesirable effects. Chemically it is amylene hydrate carbamate prepared by the action of chloride of urea on amylene hydrate. Its hypnotic action is ascribed to the presence of amylene hydrate (tertiary amyl alcohol), but on account of its penetrating odour and objectionable taste the administration of this without further combination was inexpedient. By converting the hydrate into a salt of carbaminic acid, amylene hydrate is now presented in a solid form with pleasant properties and the resulting compound is known as aponal. A series of physiological experiments is quoted which show that this compound in suitable doses produces healthy sleep, and the patients upon whom it has been tried are stated to experience a feeling of relief and freshness which follow natural sleep. All new hypnotics, however, should be tried with caution.

New Inventions.

A "CORNEAL CURETTE."

THE general practitioner frequently has to treat cases of a foreign body in the eye. When it is situated in the usual position, on the palpebral conjunctiva of the upper lid, he usually has no difficulty in dealing with the case. Not infrequently, however, the particles of cinder or steel alight upon the cornea and may have become embedded in it by the time the practitioner sees the case. Unaccustomed to the operative treatment of eye cases, he has some diffidence in attacking the cornea with a sharp instrument. In such cases a little corneal curette which has been devised by Dr. John M. Wheeler of New York will be of service. It resembles an ordinary discission needle, the point of which has been bent on the flat into a semicircle. It is impossible with ordinary care to penetrate deeply into the cornea with this instrument, whereas it is easy by a rotatory movement around the long axis to gouge out a foreign body.

A SALINE DROP REGULATOR.

WITH all the existing forms of continuous infusion and proctoclysis apparatus there is a certain amount of difficulty in regulating the flow of the saline fluid. To overcome this, Messrs. Allen and Hanburys, Limited, of Wigmore-street, London, W., have made to my instructions a simple drop regulator, as shown in the accompanying illustration. The barrel is made from toughened annealed glass, and the nickel-plated metal mounts at either end for attaching the indiarubber tubing are securely cemented on with metallic solder, thus allowing the regulator to be efficiently sterilised either by boiling or steam. The stopcock of the regulator can be adjusted by the surgeon before leaving the patient, so that any required number of drops may be administered during a given period. The glass barrel then readily allows the dropping rate of the solution to be kept under observation, and the nurse in charge of the case can easily check the rate of flow by counting the number of drops passing through the extremity of the inner indicating tube, altering the rate of flow, if necessary, by the use of the stopcock. This simple device obviates the need for spring clips, and in practice will be found extremely efficient for proctoclysis when used in conjunction with a simple apparatus consisting of a Thermos flask, fitted with a length of rubber tubing and a rectal pipe or catheter. It will be noticed from the illustration that the inner metal indicating tube is fitted with a bulbous extremity, thus enabling the drop regulator to be employed in an emergency as an intravenous cannula.

Harley-street, W. E. CANNY RYALL, F.R.C.S. Irel.

THE EJECTOR VACCINATOR.

THIS is an ingenious arrangement, finally perfected after many years' trial, for supplying all the material for efficient vaccination in a portable form ready for use. It consists essentially of the ordinary capillary tube which contains, besides the lymph, a new steel scarifier. The tube is hermetically sealed at both ends. After properly cleansing the arm with clean water but without antiseptics the tube is broken. In order to break the tube neatly and without waste, the upper side of the tube (see illustration) is nicked in two places; the one at the drop end close above the charge of vaccine, the other at the other end of the tube at about half an inch from the charge of vaccine. The broken parts are removed, then by gently pressing on the protruding end of the scarifier with the first finger the beads of vaccine are ejected on the arm as required. The sharp end of the scarifier can then be further protruded so as to scratch through the vaccine without causing bleeding. One tube will sometimes suffice for two vaccinations if the scarifier be withdrawn and heated for a few moments in a flame. The quality of the vaccine is stated to be tested weekly by actual use as in the case of the "C.P.P." In the course of the 12¼ years ending March 31st, 1911, during which the primitive forerunners of this simplified apparatus were in use, out of 28,851 insertions there have been 91·5 per cent. of typical vesicles and 8·5 per cent. of second class. The tubes can be obtained from Mr. Edward Darke, 167, King's-road, Kingston Hill, Surrey.

Professor Anderson Stuart, Dean of the Faculty of Medicine in the University of Sydney, Professor Warren, Dean of the Faculty of Engineering, and Mr. H. E. Barff, the Registrar, will with Earl Beauchamp, formerly visitor of the University, represent Sydney University at the Imperial Congress of Universities which will be held in London in July, 1912. This congress will be an important event in the educational history of the empire.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 18, 1911.

The National Insurance Bill.

OUR correspondence columns again contain communications which prove in unmistakeable manner the resentment aroused in the medical profession by the progress of the National Insurance Bill in committee of the House of Commons. There can be no doubt that the view of the majority of the medical profession is that the position of the profession under the Bill has not been sufficiently studied. Added to the deep feeling against contract practice that has at last found expression there is real anger at the alterations which have been made in the constitution of the Insurance Committees, tending to reduce medical representation upon these bodies to a negligible point. In these circumstances to force legislation upon the lines now indicated may bring about a struggle between the medical profession and the public, unedifying in character and all the sadder because it might have been avoided. We commend to the attention of our readers the letter of Sir ALFRED PEARCE GOULD, which appears on p. 1427 and which is strongly in confirmation of our own view that lack of time in which to consider the first principles of medical service is likely to lead to disaster. The great evil of hasty legislation is the risk of bringing about results other than those primarily intended, and indeed sometimes utterly opposed to them. When the National Insurance Bill was introduced amidst the plaudits of all parties, numberless difficulties connected with it had received but little consideration even by those responsible for it; only the broad suggestion had been laid down that pecuniary relief and medical attendance should be provided for the working classes in sickness, and that the money required for this should be provided in certain proportions by the worker himself, the employer, and the State. With all this we were in accord, but it soon appeared that those responsible for the measure had not grasped the medical side of their proposed administration in any certain manner, and were unwilling to take the needful time to arrive at the truth.

The important question of the administration of medical benefits is not the only one where haste has led to misunderstanding. Consider now the hospital question in connexion with the Bill. The claim of the Chancellor of the Exchequer has been that the Bill will provide efficient medical treatment for the working classes. An essential part of the medical treatment of the working classes is the treatment given at hospitals, almost entirely voluntary hospitals. For patients who are not confined to bed it may be possible under the Bill to provide efficient treatment—here the reasonable views of the medical profession as to the terms of medical service will have to be met. But what about the treatment in hospital of those who must be received in hospital wards? How is this treatment to be justly arranged for? For the minor affections which compel a man to keep to his bed he may be treated at home, but in the more serious conditions, and especially in those which need operative treatment, it is well-nigh impossible, as everyone knows who has any acquaintance with the subject, to treat cases among the poor satisfactorily except in the hospital. Now, it is true that nearly all of those who are to come under the scheme of National Insurance are being treated in the hospitals at the present time, and treated without any cost to the State, but under the Bill the conditions of admission will be altered. A voluntary charity will become a sort of adjunct to Government machinery, and it is quite impossible to say how far independent action will be possible. There can be no doubt that great changes will occur, and many of those who are connected with hospitals are gravely concerned at the probable and possible results to the institutions under their charge. The British Hospitals Association has through its council on two occasions expressed the opinion that the National Insurance Bill will be incomplete unless it provides for the hospital treatment which insured persons must have if their medical needs are to be covered by the Bill, and the matter has also engaged the attention of the Central Hospital Council, which represents all the chief hospitals of London. There are two aspects of the matter which have to be taken into account while we are discussing the admission of in-patients to voluntary hospitals. In the first place, we must consider the effect on the revenues of the hospitals of the fact that the employers of labour are compelled to contribute no small amount yearly to the insurance fund; secondly, we must consider the conditions under which those who are insured under the scheme can be admitted to the voluntary hospitals. There can be no doubt that there will be, at any rate at first, a grave falling off in the subscriptions from employers to the hospitals. On this point all hospital managers are practically in agreement; moreover, it does not depend on the mere opinion of the hospital authorities, for many large employers of labour have declared their intention of reducing their donations and subscriptions to hospitals when the Insurance Bill becomes law, saying that the enforced contribution to the fund will be so severe a tax on their profits that, however willing, they are unable to pay twice over for the medical treatment of their workmen. This loss in the income of the voluntary hospitals seems sure to occur—all those who are best qualified to judge are in agreement on the matter—and it will follow that the hospitals will have to close some of their wards. It was estimated in a valuable leading article in the *Hospital* last week that in London alone, for the sole use and treatment of those insured under the scheme, some 5000 beds in hospitals will be required. The figure is accounted for by reasonable calculation, and means, if it is right, that nearly half the beds in the voluntary hospitals of London would be taken up by cases occurring among the insured under the working of the Bill. It is true that some—perhaps the majority—of these cases would have reached the wards of a voluntary hospital in any case, but if the income of the hospitals is reduced, and at the same time the number of patients under the Bill is kept steadily up or is steadily increased, it must follow

either that a new source of income must be obtained for hospitals or that they must fail to discharge their liabilities.

As a matter of fact, it is not at all clear that the voluntary hospitals ought to undertake to provide treatment for insured persons, who are supposed to be insured against sickness. It is doubtful to our mind whether such a departure in administration is not an abuse of charity. If so, the solution appears to be that the State must pay the voluntary hospitals for the work they do. Yet to this there are several serious objections. In the first place, the mere amount of money required would seriously deplete the funds set apart for medical service, and in the second place the receipt of State contributions would almost certainly lead to the appointment of departmental representatives on the governing bodies of the hospitals. Some may regard such a change as necessary, but its tendency would almost certainly lead to an undesirable uniformity in the methods of the hospitals which would not work for progress. In Paris, for instance, the central administration of the hospitals has cast certain difficulties in the way of progress, for any deviations from the prescribed methods are not looked upon with approval. Even the surveillance of King Edward's Hospital Fund, excellent though it is in many ways, is tending to lead to a stereotyping of methods which may be undesirable. Further, it will have to be considered whether the medical staffs of hospitals will be willing to treat gratuitously patients for whom the hospitals are receiving payment: either a share of the money received from the State subsidy will have to go to the medical men attached to the hospitals or an additional paid staff will in each hospital have charge of the patients who are admitted under the Insurance Fund. Whichever of these schemes may be adopted, if any State funds are received by the hospitals, the very nature of the hospitals will be changed; they will be no longer voluntary charitable institutions. And if the voluntary character of these institutions be taken away it will not be long before the voluntary subscriptions and the voluntary management will disappear also. And with them much of the real life of hospitals will go. Has sufficient time been given to the consideration either of the advisability of this grave revolution or of methods to promote it or prevent it? We say, No.

A School of Preventive Medicine for Social Workers.

THAT the medicine of the future will be mainly preventive there can be no manner of doubt. Not that the reparative side of medicine can be entirely done away with, for accidents will happen, and some people at least will continue to transgress the laws of health, even though perfectly well acquainted with them and aware of the inevitable consequences of their infraction. But now that the State has come to a realisation of its vested interest in the general health, prevention must continue to come more and more to the fore; and, as in the case of other economic requirements whose infringement reacts injuriously on the body politic, so in preventive medicine conformity to the better way will necessarily be supported by legislation. Before legislation in these days, however, can become generally effective the sustaining force of public opinion must be behind it, and to arouse this the education of the public to intelligent ideals becomes of the first necessity.

Dr. NORMAN DITMAN, in an admirable paper on Education and Preventive Medicine,[1] emphasises the importance of such education, and pleads for the formation of a school of preventive medicine, so planned as to give instruction to medical men and students, health officers of all grades, sanitary engineers, school teachers and inspectors, nurses, theological students, legislators, charity society officers, social workers, and the general public. He puts forward a scheme of the various subjects of study, indicating in parallel columns to which of the several groups they are respectively applicable. The public is to be educated at the hands of all the other groups, in conjunction with the press and public exhibitions. To the educational aims of the school should be added those of research, both that of the laboratory and that into social and scientific methods. Students should be brought face to face with the conditions requiring improvements and be shown in action existing departments pertaining to health problems—e.g., tenement houses, offensive and dangerous occupations, child labour and factories, sweatshops, slaughter-houses, dairies, markets, watersheds, accident-preventing appliances, municipal methods relating to water-supply, sewage and refuse disposal, street cleaning, and the health department. The earlier part of Dr. DITMAN'S paper deals with the statistical and economic aspects of disease and injury, and describes in an admirable manner the brilliant successes that have already attended preventive medicine in regard to infectious diseases. Other diseases, of more or less unknown causation, such as cancer, diabetes, heart disease, and Bright's disease, challenge our best efforts at prevention, and illustrate the important connexion between a school of preventive medicine on one hand and hospital laboratories on the other. Finally, he deals with the class of disease and disability resulting from social evils, the control of which lies in the hands not only of the physician, but also in those of the economist, the clergyman, and the legislator—e.g., physical defects in children, preventable accidents, occupational diseases, insanity, alcoholism, and other relations of disease to poverty and crime. "Disease, crime, pauperism, insanity, and preventable accidents," says the author, "are the greatest blots on the modern civilised State, and the responsibility for the amelioration of these causes must be faced, upon the last analysis, by the medical profession. But the education of the physician in the past, while fitting him for the overcoming of isolated problems, has absolutely lacked that comprehensiveness needed to enable him to obtain a mastery of the broader economic and social problems of our modern life. For example, such a man should not only be able to cure, but should understand the problem of the prevention of disease and the investigation of its causes; he should be familiar with the methods of public health administration involving the health of the city, the State, and the country, which bear upon the purity of

[1] Education and Preventive Medicine. By Norman Edward Ditman, Ph.D., M.D. New York: The Columbia University Press. 1911. Pp. 75. Price 1s. 6d. net.

food and water-supplies, the existence of dangerous occupations, and the occurrence of epidemics. He should be a master of sociological questions involving the habits of the people and the evils of tenement house existence. He should be familiar with methods of municipal finance and government, questions of commerce, economics, and medical jurisprudence. He should be conversant with the mental, moral, and physical aspects of educational questions." But it is certain that if so much is asked of the exponents of medicine intelligent help must be demanded of the public.

It would be hard to find a more comprehensive statement of the legitimate—and inevitable—field of modern medicine. An ingenious illustration of public education in such matters is recorded in the *Boston Medical and Surgical Journal* of Oct. 26th. At the City Budget Exhibit in Boston recently a play, written by a twelve-year-old girl who is one of the "little mothers" that the Health Department has recently been organising into leagues and instructing in the care of babies, was performed by her child companions. It represented a tenement house in which an infant was suddenly taken ill. Well-meaning but ignorant neighbours rush in with unsought and absurd advice, and all is confusion. Presently one of the "little mothers" comes in and takes charge. At her direction one neighbour ministers to the baby, another telephones for a medical man, a third is sent to the nearest milk station, and so forth. Such an incident demonstrates not only that effective public education can be given, but how it can be given. The medical man must first lead the way.

Medical Men and Municipal Honours.

THE Lord Mayor's Show—the traditional civic pageant which astonishes us annually by the extraordinary attraction that it exercises for the London crowd, but which demonstrates no less the respect of Londoners both within and without the historic boundaries for the corporation of the greatest city in the world and for its appointed head—has come and gone. This year, as all are aware, the Chief Magistrate has been found in the person of Sir THOMAS CROSBY. Whatever Sir THOMAS CROSBY'S other claims may be to fill the office associated with the names of London's merchant princes and commercial magnates, and no doubt they are many and good, for the medical profession the chief interest in his election lies in the fact that he is one of our own calling, who has connected himself intimately with the municipal life of the City of London, and who has proved that a successful physician can secure for himself the highest civic honours by bringing to bear upon the problems of social administration the virtues of honesty, industry, and accuracy that make for distinction in the pursuit of our science. If, however, this is the first occasion upon which a member of the medical profession has assumed mayoral duties in the City of London, it has been often otherwise in provincial boroughs. Many of our towns, great and small, in the provinces may claim by this method to have set an example of progress which for our part we hope to see followed more widely in every coming year. A list of the medical men who have now taken their seats as mayors for the ensuing year will be found upon p. 1447. We wish them every success in their high office, and we congratulate them no less because they have achieved positions honourable to themselves than because their having done so will, we feel sure, act as an incentive to many of their professional colleagues, who will endeavour to combine participation in municipal life with the pursuit of a profession in itself arduous and charged with grave responsibilities for its members.

Four years ago[1] we wrote of medical men in connexion with municipal life, for in that year recognition had been accorded to several by election to the office of mayor. Among them we congratulated Mr. N. W. FAIRLES-HUMPHREYS, who had already been mayor of Montgomery on eight occasions. We are glad to observe that he now enters into his thirteenth year of office. Wimbledon had then elected Dr. S. R. COLLIER; it now places another medical man in the chair of office in the person of Surgeon-General E. L. MCSHEEHY. Saffron Waldon in re-electing Dr. J. P. ATKINSON has been true to its past precedents, established not only during the present century but by the election of 17 medical mayors in the nineteenth century, and of six during the latter part of the eighteenth. A feature in the current list to which reference may be made is the presence of medical men as mayors in the south and west of England not observable in the list of 1907. Barnstaple, Exeter, and Lewes are the boroughs to which we refer in congratulating respectively Mr. J. R. HARPER, Dr. C. J. VLIELAND, and Mr. H. STOTT. These, with their medical colleagues who have attained the office of mayor in other boroughs, or who perhaps occupy less exalted seats upon municipal councils, will certainly have no less onerous duties to perform in the future than they have had in the past. On the contrary, the tasks of all who are undertaking local administration to-day, whether as members of urban or of rural authorities, are constantly being rendered more exacting, more complex, and more responsible, while it is upon the man with medical training that the increased responsibility falls most heavily, for it is he whose sphere of influence is constantly being enlarged by the new functions imposed by recent legislature. The advent of medical men to boards of local administration is a healthful sign of the progress of preventive medicine. During the last four or five years measures for the promotion of the public health have been passed of far-reaching significance, and while the field of preventive effort has been widened the development of measures to cope with the troubles so ascertained has been gradual. When the National Insurance Bill, now making its forceful way through the House of Commons in the hands of the Chancellor of the Exchequer, commences its effective existence as an Act of Parliament, whether that be now or later, the medical man in municipal life will, indeed, to use a popular phrase, "find his work cut out for him."

The administration of the Act will be in the hands of

[1] THE LANCET, Nov. 27th, 1907, p. 1473.

Insurance Committees upon which the insured persons will be very fully represented, whether members of the approved societies or not. They will have a numerical majority of at least one-third as compared with the other members of the committee, and of the minority only two, or in certain events three, will be elected by the medical men of every locality covered by the committee. Of the rest of the minority, as we have termed it, the measure enacts that "one-half shall be appointed by the council of the county or county borough," and the rest "shall be appointed by the Insurance Commissioners." The sources from which these members of the committees (exclusive of the two members to be elected by the medical men of the locality) are to be drawn are thus defined: "The members appointed by the council of the county or county borough shall consist wholly or in part of members of the local sanitary authorities, and two at least shall be women, and of the members appointed by the Insurance Commissioners one at least shall be a duly qualified medical practitioner and two at least shall be women." It is therefore obligatory that there shall be one medical practitioner upon every Insurance Committee, and it is intended, but not in terms rendered obligatory, that two more shall be elected to it by their medical colleagues, which constitutes a representation of three medical men out of a possible 80, which, regarded numerically, is very small. A most practical and important manner of increasing medical representation will be the availability for appointment by the county or borough councils of medical men who as members of the sanitary authority have impressed upon their neighbours their fitness for selection. Moreover, there is no reason why the Insurance Commissioners should not appoint more than the one member of the medical profession whom they are obliged to nominate if there are suitable men available for the purpose. In these circumstances the inference which we draw from the provisions of the National Insurance Bill, so far as they are practically settled, considered side by side with the mayoral elections, to which we have called attention, is that it is becoming more and more valuable to a community to be able to impress medical men into active municipal life. Now that sanitary matters are receiving so much attention, the medical local councillor must necessarily have opportunities to make his influence felt among his lay colleagues, quite apart from such questions as the administration of medical benefits under the National Insurance Bill or the consideration of the interests of his profession and of its members. It is for this reason that we welcome such proof of the successful adoption of civic life by medical men, as we have called attention to in connexion with the assumption of mayoral duties by medical practitioners.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner of the Hospital and School will be held at the Trocadéro Restaurant, Piccadilly-circus, W., on Wednesday, Dec. 13th, at 6.45 for 7.15 P.M. Mr. Stanley Boyd will take the chair. Applications for dinner tickets, price 7*s.* 6*d.*, should be sent not later than Dec. 1st to the honorary secretaries, Dr. A. G. Pnear, 47, Weymouth-street, W., or Mr. T. P. Legg, 139, Harley-street, W.

Annotations.

"Ne quid nimis."

THE PRESIDENCY OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AS we announced last week, a special meeting of the Council of the Royal College of Surgeons of England was held on Thursday, Nov. 9th, to receive the resignation of Sir Henry Butlin of his office as President of the College owing to ill-health. The whole medical profession will join in the regret which was expressed by the Council at Sir Henry Butlin's retirement and at the cause thereof, will trust that that cause will soon disappear, and will endorse the warm tribute which was then paid to him by a unanimous resolution of the Council. The late President held his important post with the greatest distinction and ability, and his services to the profession and the College will long be remembered. His tenure of office was remarkable for the fact that during a large part of it he discharged also the duties of President of the British Medical Association, and in both capacities earned the highest regard of those whom he led. Sir Henry Butlin's industry, his courtesy and fairness, and his gift of oratory, quite apart from his eminence as a surgeon, peculiarly fitted him for the position of titular surgical head of the profession, and it is greatly to be regretted that his physical powers have not proved equal to the heavy and continuous strain which his public duties have thrown upon them. All will unite in wishing him improved health now that he is free from the cares of office. His successor has been well chosen, and the Council of the College may be congratulated upon electing to the chair Mr. Rickman J. Godlee. The new President, as is well known to our readers, is surgeon to University College Hospital, Holme Professor of Clinical Surgery in the medical school of that hospital, and an honorary surgeon to the King. He has already done good work upon the Council of the College.

THE NEW MEDICAL OFFICER FOR THE COUNTY OF LONDON.

THE London County Council, on Nov. 14th, had before it the question of appointing a successor to Sir Shirley F. Murphy as head of the public health service of London, which, as reorganised, is to include the superintendence of the medical inspection and treatment of school children hitherto under the control of the education department, in circumstances which have been the subject of frequent comment in THE LANCET. The General Purposes Committee reported to the Council that 33 applications for the position of medical officer had been received, and these had been referred to a special subcommittee, on which the Public Health and Education Committees were represented. The subcommittee made a preliminary selection of 14 candidates whom they interviewed, and finally six candidates, chosen from these, attended before the General Purposes Committee. The committee had also seen Dr. James Kerr, the medical officer (education). After careful consideration of the merits of each candidate, the General Purposes Committee recommended: "That William Heaton Hamer, M.A., M.D., D.P.H. Cantab., B.Sc. Lond., M.R.C.S. Eng., F.R.C.P. Lond., be promoted, as from Jan. 1st, 1912, to be medical officer of health, and be appointed also school medical officer

for the County of London, at the commencing salary of £1250 a year." At the same time, to comply with a standing order that requires more than one name to be submitted to the Council, the Committee also mentioned the names of William James Howarth, M.D., Ch.B., D.P.H. Vict., medical officer of health for the County of Kent, and Harold Scurfield, M.D., C.M. Edin., D.P.H. Cantab., medical officer of health of the city of Sheffield. Mr. H. J. Greenwood, chairman of the General Purposes Committee, in moving the appointment of Dr. Hamer, said the committee and a special subcommittee had given to the question of this appointment the careful consideration its importance warranted. Whilst possibly there might have been some disappointment at the comparatively small number of applications for the post, it was generally felt that out of the 33 applications received there was certainly not a small number of gentlemen who were quite worthy by reason of their experience and attainments to be considered for the position. He was very glad heartily to commend to the Council the recommendation of the committee. Dr. Hamer's services were so well known that it would be almost an impertinence to go into them in detail. He had been in the service of the Council for almost 20 years, and the position he had held under the late medical officer of health, Sir Shirley Murphy, had afforded him experience in all the wide and intricate branches of the work that came within the scope of the Public Health Department. At the same time, under Standing Orders, the committee submitted the names of two other gentlemen, both candidates of the greatest ability and well known for their services, in one case to the city of Sheffield, and in the other to the county of Kent. Although it was true that both these gentlemen had had active experience in the new duties which it was proposed to cast in future upon the London County Council Public Health Department—viz., the superintendence of the medical inspection and treatment of school children—yet the General Purposes Committee felt that that experience, though valuable, was limited as compared with the natural needs of London, and had been gained in circumstances which to a large extent would not obtain in the metropolis. Naturally, Dr. Hamer had not had the opportunity of showing his ability in the particular direction of school medical work, but his many other attainments and enormously superior position in almost every other detail of his work left no doubt in the mind of the committee that of the three candidates he was the one the Council should appoint. Mr. Greenwood expressed the conviction that in appointing Dr. Hamer the Council would be selecting a gentleman who would not only fill the position to the very utmost of his ability, but to the greatest credit of the Council and of the County of London. The proposal was accepted without further debate and amid a general chorus of approval, to which chorus we take the liberty of adding our own voice.

LATE OR RETROGRADE INFANTILISM OF THE ADULT.

SOME five years ago M. Ch. Gandy, at a meeting of the Société Médicale des Hôpitaux de Paris, showed two patients presenting a peculiar dystrophic syndrome, which concerned more particularly the sexual system. Each of the patients had attained the full normal development of the adult, but some time after the age of 30 a gradual and striking change set in, consisting of a regression of primary and secondary sexual characteristics. The genitalia atrophied and lost their functional capacity; the hair of the moustache, the chin, the axillæ, and the pubes began to fall out. From a state of virility the patients sank into a sort of infantilism such as is found in the pre-pubescent period. On June 23rd of this year M. Gandy exhibited another still more striking case of retrograde infantilism at a meeting of the same society. The patient was a man aged 42, who had been married twice, and had had three children. Some 12 years previously, at about the age of 30, certain somatic alterations had very gradually made their appearance, without obvious cause. The parts usually covered with hair (the scalp not included) had become bare, sexual impotence and atrophy of the genitalia had set in, and the face, hands, and feet had become puffy. On examination it was noted that the face had a curious waxy pallor, and was smooth like that of a child, with the exception of a few short hairs on the chin; the skin was dry and showed very fine folds, especially on the forehead and on the lower parts of the cheeks. The skin of the trunk and limbs was equally pale, smooth, fine, and soft; there was little or no subcutaneous fat; the nipples were small and devoid of all pigment. A very few short, fine hairs were left on the pubes. The external genitalia resembled those of a child; the penis, scrotum, and testicles were all small. No trace of the thyroid gland was discoverable by palpation. There was no alteration of the visual fields, no polyuria or glycosuria. The only previous illness of any significance was a left gonorrhœal orchitis of about 14 days' duration, which had developed about the same time as the commencement of the general symptoms. Some 18 cases of the condition, of which only two concern the female sex, are now on record. It is quite possible that at least some of the cases described as degeneratio adiposo-genitalis of hypophyseal origin (Fröhlich) ought to be regarded as closely associated to the syndrome under discussion. The main features of the condition are (1) its development after puberty is established in subjects who have all the normal secondary sexual characteristics; and (2) its selective dystrophic action on all that pertains to the sexual sphere. Apart from this, the changes in the skin are specially noteworthy, for they are certainly closely akin to what obtains in myxœdema. The puffiness, smoothness, pallor, and the finely folded, finely wrinkled skin are just such as are met with in that disease. The whole appearance of the patient affected with retrograde infantilism is unmistakeable, but sometimes other symptoms are present and may be considered part of the syndrome. Mental apathy and indifference may be noted; muscular enfeeblement is frequent; the pulse is small and the arterial tension low. Occasionally a sort of diabetes insipidus occurs, with polyuria and polydipsia. Once the condition is established no further change ensues, as a rule, and the patients may remain as it were immobilised in this infantilism for years. M. Gandy is of the opinion that the pathogenic basis of the disease is the combination of thyroid and testicular impairment. In three cases where a pathological examination was made the thyroid was markedly atrophic and showed unmistakeable inflammatory and sclerotic changes, whereas the appearance of the testicles suggested rather a simple regressive atrophy. It is difficult to say whether the pituitary plays any part in the development of the condition, and equally difficult to adjudicate on the relative importance of what seem to be the more definite pathogenic factors. In fact, though a general pathological agent may act on several of the glands concerned with internal secretion, producing recognisable lesions in them, it does not follow that these are a proof of the participation of the glands in the genesis of the syndrome; such lesions cannot by themselves be held to demonstrate a pathogenic rôle on the part of the glands concerned, as Brissaud maintained. Not a few cases of testicular atrophy are on record where no symptoms that might be ascribed to testicular insufficiency developed. Karakascheff has published a case of this type of infantilism where the main pathological lesion was atrophy of the suprarenal glands. Where definite signs of feminism

(hypertrophied mammary glands, &c.) supervene on the establishment of retrograde infantilism, as in cases reported by Lereboullet and Josserand, the problem becomes still more complex.

THE NATIONAL INSURANCE BILL: AN IMPORTANT MEETING.

A MASS meeting of the medical profession in Lancashire and Cheshire has been called for to-day (Saturday, Nov. 18th), at 3.30 P.M., in the Midland Hotel, Manchester, to discuss the medical clauses of the National Insurance Bill, and to pass a resolution stating that as at present framed the Bill does not embody the demands of the medical profession, that it is unworkable, and dangerous to the public health. All members of the medical profession in Lancashire and Cheshire are earnestly requested to attend.

SOME OBSERVATIONS ON THE DECOMPOSITION PRODUCTS OF SUGARS.

IN spite of the large amount of research which has been devoted to the elucidation of the problems of the metabolism of sugar in the animal organism, it must be confessed, as Abderhalden has stated, that exact details of the processes of oxidation of glucose, the sugar chiefly concerned, are wanting. Some interesting observations, made from a chemical standpoint by Professor Adolf Jolles, of Vienna, and published in the *Wiener Medizinische Wochenschrift* of Nov. 4th, seem calculated to throw considerable light on this subject and to stimulate further research from a physiological aspect. He has investigated the action of various oxidising agents upon a number of different sugars, including arabinose, rhamnose, dextrose, lævulose, invert sugar, mannose, galactose, cane sugar, maltose, and lactose in weak alkaline solutions at 37 °C. In general the strength of the solutions was 1 per cent. of sugar made N/100 alkaline with sodium hydrate. In every case with the exception of cane sugar a diminution in the rotating power of the solution occurs together with the formation of acids. The alteration in the rotating power had been demonstrated previously by Lobry de Bruyn and van Ekenstein. Professor Jolles has devoted his experiments chiefly to the determination of the acids formed. He finds that neutralisation of the alkali produces marked slowing in the formation of the acids, while with glucose in N/100 acid solution acid formation does not occur and the sugar remains unaltered. By means of the addition to the solutions of hydrogen peroxide the oxidation processes were accelerated, occurring more quickly than when the oxygen in the air was used as the oxidising agent. Lævulose was found to produce more acid than dextrose, and therefore to be more easily oxidisable. The oxidation products obtained comprised ethyl alcohol, acetaldehyd, acetone, formic, acetic, butyric, lactic, glycolic, oxalic, succinic, aceto-acetic, and glycuronic acids. With most sugars the chief product was formic acid, a very small quantity of acetaldehyd and an acid which gave Tollen's naphtho-resorcin reaction for glycuronic acid. Lactic acid was only obtained in alkaline solutions of dextrose without the addition of hydrogen peroxide. The use of oxide of silver as an oxidising reagent gave similar results to those obtained with hydrogen peroxide. Ammonia and sodium carbonate do not influence the decomposition of sugar as strongly as sodium hydrate. Professor Jolles has developed his researches in several ways. Since cane sugar does not undergo the same decomposition in alkaline solution as the other sugars, he has utilised this property to develop a method for the quantitative estimation of cane sugar in the presence of other optically active sugars. He makes the mixture alkaline, keeps it for 24 hours at 37° C., by which time the other sugars have become optically inactive, and hence the cane sugar can be determined from the difference in the rotating power of the solution at the beginning and the end of the experiment. He has also devoted much attention to the formation of glycuronic acid. This acid has been found in the urine and the blood and in the liver, but always in combination, usually with phenol, indol, or skatol. The usual quantity is small, but is increased by the administration of certain substances such as chloral hydrate, camphor, and menthol. The composition of this acid suggests its probable origin in the body from glucose, but according to Professor Jolles the direct demonstration of this was wanting before his own experiments. He describes in detail the method of obtaining glycuronic acid from sugar and the tests he employed for its identification. He proceeds to apply his observations upon the decomposition of sugars *in vitro* to the elucidation of the problems of glycolysis in the organism. Lépine has regarded the breaking up of glucose in the body as due to a glycolytic ferment present in the blood and tissues. Cohnheim has isolated from the pancreas a substance which can activate the glycolytic ferment present in the muscles. Professor Jolles is of opinion that the conditions of his experiments approximate to those in the body. The blood with its definite alkalinity permeates the tissues, and the peroxidases, catalases, and other oxidising ferments can be regarded as exerting a similar action to the hydrogen peroxide in his chemical experiments. He suggests that the sugar in the tissues is oxidised to acids of low molecular weight, such as formic acid, which are further oxidised in the blood to carbon-dioxide and water. He also shows how his observations can be adapted to explain glycolysis in muscle, the formation of sarcolactic acid, of glycuronic acid, and even some of the features of diabetes and pentosuria. He is careful to state, however, that these speculations are hypothetical and are not supported by physiological experiments. His observations are certainly suggestive and are worthy of careful consideration. They should form the basis of further physiological work upon this question of glycolysis in the body.

BACTERIOLOGY OF CONJUNCTIVITIS.

THE differentiation of various forms of conjunctivitis by an investigation of their bacteriology has been of the greatest clinical value. Progress in medicine is associated with the subdivision of large groups of cases having broad clinical resemblances into smaller groups separated from one another on etiological grounds, and ophthalmic practice furnishes good examples of this process. By simple smear preparations of ocular secretions results of great practical importance are quickly and readily obtained, as the various organisms associated with varieties of conjunctivitis can be recognised with some certainty by their morphology, and appropriate treatment may be at once commenced. Axenfeld is indeed inclined to consider that cultural methods rarely yield better results than simple examination, and may indeed lead to mistakes owing to the growth of saprophytes which may mask the more important pathogenic organisms which are often of difficult culture. An interesting paper [1] by Dr. J. P. McGowan and Mr. W. Macrae Taylor shows, however, that the examination by culture of the organisms present may lead to a further differentiation of cases which would otherwise be confused. They record a school epidemic, involving from first to last some 49 patients, which would have been regarded as an outbreak of pneumococcal conjunctivitis had the diagnosis been made on the examination of simple smear preparations. In all the cases examined, five in number, an

[1] THE LANCET, Nov. 11th, 1911, p. 1324.

organism was isolated which, while morphologically identical with the pneumococcus, nevertheless differed from that organism, as usually described, in its fermentative activity, the character of its growth in rabbit serum, and especially in its complete non-pathogenicity for those animals which are usually highly susceptible to the pneumococcus. The organism thus separated and carefully studied certainly differs in important respects from the typical pneumococcus, though opinions may possibly differ as to whether these variations could be regarded as of specific value in such a notoriously variable member of that highly variable group, the streptococci. It is, however, by such accurate and careful investigations that we hope for advance.

THE RAG FLOCK BILL.

THE Rag Flock Bill was read a third time and passed in the House of Commons on Tuesday last, and was introduced into the House of Lords on the following day. The measure, an unquestionably important piece of sanitary legislation which has been demanded for a long time, will undoubtedly receive the Royal assent in the course of a few weeks. Our own practical inquiries have shown that when uncontrolled in regard to the cleansing of the rags by thorough washing, the rag flock business may easily be a menace to the public health. When it is remembered how filthy the raw materials can be, it is evident that the public need some efficient protection in this matter. We believe that when the provisions of the measure are thoroughly enforced the reproach that has long hung over the industry will be removed, and further that the interests of the trade will gain rather than suffer.

THE PHYSIOLOGICAL STANDARDISATION OF ERGOT.

THE latest contribution to our knowledge of ergot comes in the form of a Bulletin[1] by Dr. C. W. Edmunds, of the University of Michigan, and Dr. Worth Hale, of the Hygienic Laboratory, Washington, D.C. The investigation was undertaken with a view of ascertaining which of the many methods of standardising ergot is best suited for the purpose. Kobert, whose labours have thrown considerable light on the composition of the active principles of ergot, described this drug as one of the most important medicines, but one of the hardest to estimate. The authors of the Bulletin preface their own work by an illuminating historical summary of the methods now in use for standardising ergot, with full abstracts of many important recent papers that are not accessible to the majority of readers. The importance of establishing a standard method of assay is well illustrated by an incident that occurred in England in 1909. A specimen of a fluid extract of ergot was submitted to three different physiological experts, one of whom condemned the sample, while the other two considered it satisfactory. The cock's-comb, uterine, and blood pressure methods were tried with a series of fluid extracts and special preparations of ergot, and the results were compared with those derived from the chemical determination of the cornutin of Keller and the amount of benzol extractive. These chemical methods showed but little relation to the biological methods, and the authors consider that the latter should be used as a means of insuring to those who require the drug a remedy both potent and of uniform strength. For this purpose the cock's-comb method is recommended on practical grounds in preference to the uterus method. These two methods yielded almost identical results, and they may therefore be taken as indicating the true relative strengths of the different specimens. It was found that an absolute parallelism does not exist between the uterine and the blood pressure action of ergot. This may possibly be accounted for by the probability that in the process of manufacture an unusually large amount of putrefactive amines may have been formed, which would have the tendency to raise the blood pressure value without increasing the strength of the preparation as measured by its action on the uterus. These results are interesting, inasmuch as the cock's-comb method has been unfavourably reported upon whenever it has been mentioned in the literature of the past few years, doubt having been thrown on its value as a criterion of the therapeutic activity of preparations of ergot when applied to the human uterus. The examination of many leading pharmaceutical preparations of ergot by these different methods led to the conclusion that such preparations should be marked with the date of manufacture, as they deteriorate quite rapidly. From the standpoint of both physician and patient an interesting part of the research relates to the varying activity of the leading American preparations of ergot. The fluid extracts examined differed greatly in strength, some being only about one-fourth as strong as a preparation freshly made from Spanish ergot. Non-pharmacopœial preparations showed even greater discrepancies between the strengths claimed and those actually found. For example, one proprietary preparation, stated to be two and a half times as strong as a fluid extract, was found by experiment to be only one-third the strength of a fluid extract. Indeed, it was 50 per cent. weaker than a fluid extract made by the same firm. It is suggested that makers of preparations of ergot should refrain from using such phrases as "ergot in permanent solution" in their advertising literature until more reliable methods of manufacture are devised. The practical application of this valuable research into the literature and physiological action of ergot and its preparations is obvious. Physicians will do well to employ only reasonably fresh preparations of the drug, made with care so that putrefactive changes may be avoided as far as possible. Needless to say, the drug itself should be not more than one year old, free from mould and sound in every way.

THE SENSE OF PRESSURE IN THE FACE, EYE, AND TONGUE.

IN the current issue of *Brain* there is an article by Dr. W. J. Maloney, of Fordham University, New York, and Dr. Foster Kennedy, of Cornell University, New York, on the sense of pressure in the face, eye, and tongue, that contains a record of original investigations which may prove to be important. Notwithstanding the large amount of attention that has been directed to the question of the sensory innervation of the face, there are still certain points on which our knowledge is very incomplete. One of these is the problem as to whether the fifth or the seventh cranial nerve, or both, or neither, but some other quite different nerve, conveys afferent impressions from the deeper parts of the facial tissues. The evidence drawn from an examination of cases in which the Gasserian ganglion had been removed for trigeminal neuralgia has been so contradictory that Dr. Maloney and Dr. Kennedy determined to reinvestigate the matter for themselves. Their material comprised eight cases of removal of the Gasserian ganglion and ten cases of complete peripheral seventh nerve palsy from lesions at various levels, arising from several causes, in addition to certain cases of fifth or seventh nerve palsy from central lesions. Pressure-touch, pressure-pain, and the localisation of these were carefully tested on the affected face, eye, and tongue. With the pressure-sense of the tongue the peripheral hypoglossal nerve appears to have nothing to do, for in two cases of

facio-hypoglossal anastomosis for facial palsy, in which the twelfth nerve had been cut across and re-establishment of continuity rendered impossible, there was no alteration of that sense whatever. Nor do the fibres underlying it run in the chorda tympani, since three cases of facial palsy in which there was clear indication that the latter was implicated showed no defect of pressure-sense either. On the other hand, the Gasserian ganglion cases established the fact that the pressure-pain fibres for the eye are invariably affected by removal of the ganglion. The loss on the cheek to pressure-pain is always less than on the forehead, and on the lips than on the cheek. A critical consideration of their results leads Dr. Maloney and Dr. Kennedy to conclude that the fibres conveying impulses from pressure-touch probably run in the peripheral branches of the fifth nerve and certainly enter the Gasserian ganglion, but there is evidence to show that there are alternative courses for certain impulses connected with deep sensibility. These alternative nerve mechanisms are the seventh nerve and the sympathetic. Some of the cases examined make it clear that certain at least of the pressure-pain fibres from the face are associated with the facial nerve in the Fallopian canal, but they must pass through the region of the fifth nerve roots before entering the canal. Dr. Maloney and Dr. Kennedy suppose they run by way of Meckel's ganglion and the Vidian nerve to the geniculate ganglion. After the seventh nerve leaves the canal it is purely motor in function. It is possible that the sympathetic system conveys certain pressure-sense fibres associated with a general crude sensibility to pressure-pain, and that the intactness of this system explains the conservation of pressure-pain in the tongue under the circumstances described above. On the other hand, the involvement of the system from injury to carotid and cavernous plexus fibres at the time of operation may explain the permanent loss of pressure-pain in the eye and forehead on the affected side in the gasseriectomy cases.

CEREBRAL ABSCESS COMPLICATING AMŒBIC DYSENTERY.

IT is not surprising that the amœba coli, which so often infects the liver by way of the portal vein, should occasionally reach other organs and tissues through the systemic circulation. Indeed, a general dysenteric pyæmia might be expected to occur more frequently than is actually the case. An occasional and important consequence of diffusion of the amœbic infection is suppuration within the brain. Professor O. Jacob, writing in the *Revue de Chirurgie* for October, has collected records of nine cases from the literature, mostly by French authors, to which he adds a very full description of two cases under his own care. The first record was made by Julien in 1864, and, as in all the others, concerned a case of cerebral abscess complicating dysentery, in which hepatic suppuration had already occurred. The amœbic nature of the lesion was proved in four cases only, including the two reported by Jacob himself; in the others it was possible or probable that suppuration was provoked by other and secondary infective agents. Cerebral abscess occurs, according to Kartulis's observations in Alexandria, in over 3 per cent. of all cases of purulent dysenteric hepatitis; and though this is higher than the usual experience of tropical clinicians would indicate, it is probable that a routine examination of the cranial contents in all necropsies, such as Kartulis practised, would yield a similar result. Men are affected much oftener than women, and the age of the patient always lies between 20 and 50 years. Suppuration within the skull appears more likely to occur if the hepatic abscess communicate with the respiratory tract. No part of the brain is specially liable, but so far no case has occurred within the cerebellum. The abscess is usually single, and attains the size of a large egg. Meningitis is the exception, and consequently lumbar puncture yields a clear fluid. There is no encysting membrane, the abscess being in actual fact a necrotic area, softening to the consistence of pus in the middle and delimited by an inflammatory zone. Microscopic examination will discover the presence of amœbæ in this limiting area. The symptoms are not different from those of cerebral abscess in general; there is headache, which may or may not be localised in the region affected, the toxic evidences of suppuration are not conspicuous, and there is almost no proof of increased intracranial tension. Localising phenomena may or may not be present, according to the site of the lesion. Jacob in one of his cases was enabled to trephine over an abscess in the right temporal lobe and drain it, by the discovery of left bilateral homonymous hemianopsia and paresis of the left arm. Neither in this case nor in the other which he reports, however, was the operation successful in saving life; and as these are the only examples of surgical treatment hitherto recorded, the history of amœbic abscess of the brain is up to now one of uniform failure. One or two suggestions of importance in regard to technique are worthy of record. Extensive trephining is necessary, and the abscess should be sought for with a channelled sound and not with an aspirating needle, since the pus is viscid and runs reluctantly. For the same reason it is essential to provide freely for drainage. Possibly an earlier attack upon the disease may in the future give happier results.

SO-CALLED SYNONYMOUS PRODUCTS.

A GOOD deal has been said and written concerning the practice, which seems to be growing rather than diminishing, of marketing medicinal articles, identical in composition, under a variety of protected names. The subject, both in its legal and common-sense aspect, was fully discussed in THE LANCET of Nov. 17th, 1906, p. 1391, and on more recent occasions has been dealt with from other points of view. The literature of the subject is, in fact, extensive, and additions to it are being made constantly. In the *Pharmaceutische Zeitung* of April 26th, p. 327, there appeared a translation of an article contributed to the Russian "Official Medical Almanac" for 1911 by Professor B. J. Slowzow, in which the question is approached from a practical standpoint. He deplores the bewildering multiplicity of "new medicinal agents," many of which are merely imitations of, or are claimed to be synonymous with, well-known synthetic products, and shows that many of the preparations which are claimed to be of the same chemical composition as well-known branded products differ from them materially. The question arises as to what results must be expected from the employment of "imitations," and in this connexion he gives instances showing how a well-known product got a bad name because a "synonymous" article which had been substituted caused "œdema of the nasal mucous membrane and violent perspiration." Professor Slowzow suggests that medical practitioners could do a good deal to improve matters by the simple process of adding the maker's name when prescribing this or that preparation. This is not so simple as it seems, for the difficulty is in finding out which maker's name to add.

IN view of their departure for India the Duke of Teck and Viscount Iveagh, two of the three Governors of King Edward's Hospital Fund for London, have, with the approval of His Majesty the King, Patron of the Fund, and the concurrence of the Speaker of the House of Commons, appointed the Earl of Donoughmore, Lord Chairman of Committees of the

House of Lords, and the Right Hon. Sir T. Vesey Strong, Bart., K.C.V.O., to act with the Speaker as a committee to exercise the powers of the Governors until their return.

THE British Institute of Social Service and the National League for Physical Education and Improvement are holding a joint conference on "Some Preventive Measures against Consumption" in the library of the institute, 4, Tavistock-square, on Wednesday, Nov. 22nd, at 5 P.M. Free tickets of admission may be obtained on application to the secretary at that address. The chair will be occupied by Dr. Arthur Newsholme, chief medical officer to the Local Government Board.

AT the meeting of the Medical Society of London held last Monday Dr. F. W. Mott opened an interesting debate upon the Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System in words which we reproduce in full in another column of THE LANCET. An interesting debate ensued thereon, which has been adjourned until Monday next, Nov. 20th.

AT the seventh annual public meeting of the Association of Women Pharmacists, to be held in the lecture theatre of the Pharmaceutical Society, at 17, Bloomsbury-square, W.C., on Monday, Nov. 20th, at 8 P.M., an address will be given by Professor W. E. Dixon on the Relation of the Pharmacist to Therapeutics.

Dr. Henry Curwen has received the King's Royal Licence to accept and wear the decoration of the Fourth Class of the Order of El Aliyeh which has been conferred upon him by the Sultan of Zanzibar in recognition of valuable service rendered while employed under the Zanzibar Government.

Sir Thomas Boor Crosby, M.D., Lord Mayor of London, has accepted the invitation of the Council and the Head Master of Epsom College to distribute the prizes and to address the boys on the next Founder's Day, which falls on July 27th, 1912.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ORDINARY MEETING OF THE COUNCIL.

AN ordinary meeting of the Council was held on Nov. 9th, Mr. C. W. MANSELL MOULLIN, Vice-President, being in the chair.

It was resolved to issue Diplomas of Membership to 80 successful candidates.

At the recent examination for the Diploma of Tropical Medicine, which was the first examination held, only one candidate presented himself, and he passed the examination. The successful candidate was Dr. James Bruce-Bays, of Grahamstown, Cape Colony.

A report was received from the Board of Examiners in Dental Surgery dealing with the report of the Inspector of the General Medical Council on the Final Examination for the Licence. *Inter alia* it suggests a revision of the syllabus of the examination in Surgery and Surgical Pathology, and it was approved.

A report was received from the Committee of Management; in it were considered the facts and suggestions contained in the report of the Public Health Committee of the General Medical Council. The report was received and adopted, and it was resolved to send it to the General Medical Council.

The VICE-PRESIDENT reported that Mr. Hallett had been invited by the Council on Medical Education of the American Medical Association to attend the conference on Medical Education to be held in Chicago on Feb. 28th, 1912, and address the meeting on the subject of the methods of conducting examinations for licences to practise medicine adopted by the Conjoint Examining Board in England, and that after consultation with the chairman of the Committee of Management Sir Henry Butlin had agreed with the President of the Royal College of Physicians to give Mr. Hallett leave to accept the invitation.

The VICE-PRESIDENT reported that the Bradshaw Lecture would be delivered by Mr. R. Clement Lucas on Wednesday, Dec. 6th, at 5 o'clock P.M., and that the subject of the lecture would be "Some Points in Heredity."

SPECIAL MEETING OF THE COUNCIL.

As we announced in THE LANCET of last week a special meeting of the Council was held on Nov. 9th to receive the resignation of the President, Sir Henry T. Butlin. The resignation was accepted with regret, and the following resolution was moved by Sir HENRY MORRIS, seconded by Mr. EDMUND OWEN, and carried unanimously:—

In accepting the resignation of the President of the College, as they very regretfully and reluctantly have just done, the Council desire to convey to Sir Henry Butlin the expression of their deep sympathy with him in that he has been compelled on account of illness to curtail the period during which he otherwise would have held the position of President of the Royal College of Surgeons of England.

The Council fully recognise and appreciate the intrepid and unflinching manner in which Sir Henry Butlin, in spite of imperfect health and impaired strength, has throughout performed the varied and important duties of President, and they share with him the disappointment, which they are sure he himself keenly feels, that he is not physically able to continue in office any longer.

The Council, moreover, desire to express their admiration for the ability, dignity, and courtesy with which Sir Henry Butlin has represented the College, and to assure him that the high standard of his example will always be remembered and cherished by his colleagues.

The Council then elected Mr. Rickman J. Godlee to fill the vacant post of President.

TUBERCULOSIS IN SCHOOL CHILDREN.

IN THE LANCET of Nov. 4th (p. 1278) we referred in general terms to the interesting report of the Chief Medical Officer of the Board of Education. One of the most important sections of that report deals with the various aspects of tuberculosis in school children. The subject of tuberculosis in young life has until recently received more attention in France than in this country, and the numerous institutions which have been formed for the care of "consumptive" children throughout that country, and the absence of similar provision for adults, bear a singular contrast to the methods which have been adopted in this country. With the advent of the school medical officers, however, much more attention is being drawn to the incidence of tuberculosis, especially of the pulmonary variety, in children at the school age, and the observations and suggestions to be found in Sir George Newman's report are well worthy of study.

The section to which we have referred deals with three chief issues relating to tuberculosis in children: 1. The Findings of School Medical Officers. 2. Existing Provision for Treatment. 3. Suggestions for Treatment by the Local Education Authority.

Findings of School Medical Officers.

In the first of these divisions especial stress is laid on the difficulties of diagnosis. This is shown by the considerable difference in the percentage of cases discovered in various areas. In Worcestershire, for instance, owing to the fact that one of the assistant medical officers diagnosed pulmonary tuberculosis in about 15 per cent. of the children examined, the percentage of cases discovered is 4·18. On the other hand, in Hertfordshire, out of a total of 12,772 children examined, one case of tuberculosis only was recorded. In children the diagnosis of early pulmonary tuberculosis is admittedly difficult, and must be especially so in the course of routine medical inspection; one reason is that it is more difficult to obtain sputum from children than from adults, and consequently the bacteriological test can frequently not be carried out. The von Pirquet test has been applied by some of the officers, but opinion is by no means unanimous as to its true diagnostic value.

We remark with satisfaction that the home conditions of tuberculous children have been investigated in a number of areas. This is a matter which we consider should be encouraged, if not insisted upon, wherever possible. The report states that whenever such investigations have been made the home surroundings, and particularly the sleeping arrangements, have almost always been unsatisfactory, and the need for inspection and supervision of the homes, together with the giving of advice and practical assistance, becomes increasingly evident. We have frequently insisted on the fact that the "fight against consumption" is inseparable from the housing problem, and until the slums are

cleared and the working classes are properly instructed in the need of cleanliness and of ventilation of the living rooms, but little real progress will be made towards the eradication of the disease. These remarks apply both to urban and rural districts. We trust, therefore, that the education authorities will speedily act upon the suggestions of the medical officer to the Board of Education.

Existing Provisions for Treatment.

In the second division of this section an account is given of the existing provisions for the treatment of tuberculous children. The special means already established are; (*a*) Hospitals and hospital schools; (*b*) sanatoriums and sanatorium schools; and (*c*) open-air schools, schools for physically defective (cripple) children. Institutions of these characters are but few in number, but their success shows that if more were provided much good would result.

A Scheme for the Prevention of Tuberculosis.

The third division is headed "Suggestions for the Treatment of Tuberculous Children by the Local Education Authority," and Sir George Newman very rightly remarks: "The time has perhaps come for education authorities carefully to consider their responsibilities with regard to the cases of tuberculosis among children occurring in their areas. For whilst it is true that the problem of tuberculosis, as a whole, does not come directly within the purview of the Local Education Authority, it is becoming more evident that the authority is, in fact, somewhat deeply concerned." We entirely endorse the remark that any national scheme for the prevention of tuberculosis is conspicuously incomplete without special arrangements for dealing with the disease among children, and it seems clear, therefore, as is mentioned in the report, that education authorities by means of their school medical service have the opportunity of playing an extremely important, and indeed essential, part in the prevention and cure of tuberculosis.

Sir George Newman then gives details of "A Scheme for the Prevention of Tuberculosis." In the first instance he insists that "all stages of phthisis should be notifiable, and notification should be made to the medical officer of health." The arguments which have been advanced for and against this suggestion are very forcible, and if such a proposal could be carried to its logical and practical conclusions—that is to say, if every case notified were visited by the medical officer of health, and if his directions as to the destruction or satisfactory alterations of unhealthy tenements were rigidly carried out—then, indeed, a most important step towards the prevention of tuberculosis will have been established. Notification, to be effectual, is a costly proceeding; already pulmonary tuberculosis is compulsory in institutions under the Poor-law and in all hospitals and institutions supported by voluntary contributions, and some experience of this measure as it is now practised is necessary before definite conclusions as to its utility can be formed. The establishment of "tuberculosis" dispensaries is undoubtedly a step in advance, and we agree that they should either be controlled by the medical officer of health and his assistants, or, if they are provided by voluntary associations, they should be intimately connected with the public health and school medical services. Perhaps the most important function they would fulfil would be to give practical advice as to personal and general hygiene.

The third suggestion under this scheme is as to the provision for the actual treatment of children. From the dispensary or school inspection clinic appropriate cases of the disease in children would be referred to a hospital, a sanatorium, a sanatorium school, a residential tuberculosis school, an open-air school, or a special day school. To carry this out a vast organisation would be necessary, but we believe the result would fully warrant the expense which would be entailed, for, once more to quote the report, "It is essential to the extermination of the disease that the early treatment of tuberculous children should receive attention."

In considering the relation between the pre-tuberculous school-child and the tuberculous adult there may lie one of our most important methods of checking phthisis.

Dr. A. Emrys-Jones has been reappointed a member of the medical board of the University of Wales for a further period of three years.

BRITISH MEDICAL BENEVOLENT FUND.

AT the October meeting of the committee 34 cases were considered and grants amounting to £253 made to 26 of the applicants. As the treasurer had reported that the account at the bank was already overdrawn to the extent of £95 the total deficit is now £348. Additional help is urgently needed, for applications at this time of the year are not only very numerous but most distressing. Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, W. Appended is an abstract of the cases relieved:—

Daughter, aged 66, of late M.D. St. Andrews. Only income a small annuity purchased by friends, and is in such poor health that work is impossible. Relieved four times, £48. Voted £12.

Daughter, aged 60, of late F.R.C.S. Has maintained herself as companion, housekeeper, &c., for several years, but for the last 18 months has been unable to obtain any post. Relieved twice, £10. Voted £5.

Widow, aged 56, of L.R.C.P. Edin. No income. Health very indifferent and dependent on two children who can ill afford to help. Relieved four times, £40. Voted £10.

Daughter, aged 68, of late L.S.A. No income and quite unable to earn a living. Relieved four times, £40. Voted £10.

Daughter, aged 50, of late M.R.C.S. Has had some very good posts as daily governess, but for the last nine months has been unable to obtain any work in spite of every effort. Small savings exhausted. Voted £10.

Daughter, aged 37, of late L.R.C.P. Edin. Used to maintain herself by teaching languages, but broke down in health two years ago and is still unfit for regular work. Voted £2 and given the offer of being taken in at a hospital for a rest cure before the reconsideration of her case.

Daughter, aged 48, of late L.F.P.S. Glasg. Has supported herself for some years by letting lodgings at a small seaside place, but earnings during the recent season have been insufficient to provide for the winter. Voted £10.

Widow, aged 44, of L.S.A. Unprovided for at recent death of husband, but has been promised a post in New Zealand and had the passage money provided by relations. Asks for a little help towards immediate needs before leaving this country. Voted £5.

Daughter, aged 76, of a late surgeon in the Scots Guards. Lost her income through a defaulting trustee several years ago and is now dependent on an old-age pension and slight occasional help from relations. Relieved twice, £33. Voted £15.

Widow, aged 79, of F.R.C.S. Has a small income, but being a chronic invalid is compelled to incur expenses for which it is insufficient. Voted £10.

Daughter, aged 64, of late M.R.C.S. Only income £10 per annum from another charity and is nearly blind. Relieved six times, £54. Voted £12.

Widow, aged 63, of L.R.C.P., L.R.C.S. Edin. Endeavours to support herself by letting rooms and teaching, but has lost most of her pupils and the rooms have been vacant for some weeks. Relieved 12 times, £92. Voted £5.

Widow, aged 64, of L.F.P.S. Glasg. Only income a pension of £24 per annum; children unable to help and health feeble. Relieved three times, £20. Voted £10.

Widow, aged 71, of M.R.C.S. Dependent on an old-age pension and slight assistance from children. Relieved six times, £74. Voted £12.

Widow, aged 73, of L.R.C.S. Edin. Kept a school for some years after husband's death, but has recently been practically dependent on a boarder who left a few months ago after a stay of ten years. Relieved five times, £39. Voted £5.

Daughter, aged 60, of late M.R.C.S. No income and dependent on a sister who only has two small annuities from charitable societies. Relieved twice, £20. Voted £12.

Widow, aged 71, of M.D. St. Andrews. Supported herself for several years after husband's death, but is now quite without means; children only give slight irregular help. Relieved four times, £54. Voted £12 and recommended to apply for an old-age pension.

Widow, aged 50, of L.R.C.P.I. Quite unprovided for at husband's death a few years ago, and being in feeble health is dependent on a daughter who teaches music. Relieved four times, £48. Voted £12.

Daughter, aged 52, of late L.R.C.P. Edin. No income, and quite unable to support herself owing to continuous ill-health. Relieved twice, £20. Voted £12.

Daughter, aged 59, of late M.D. Lond. Only income £7 a year, and totally incapacitated by a nervous disease. Relieved twice, £24. Voted £2, and recommended to apply for admission to an infirmary.

Widow, aged 73, of L.R.C.P. Edin. Supplements an income of a few shillings a week by letting rooms, but finds increasing difficulty in obtaining lodgers. Relieved once, £12. Voted £12.

Widow, aged 44, of M.R.C.S. No income; supports herself by letting lodgings but wants help to tide over the winter and to give a daughter lessons in shorthand. Relieved twice, £25. Voted £10.

Widow, aged 63, of M.R.C.S. No income and has just been obliged to give up a post as companion on account of a nervous complaint. Relieved twice, £24. Voted £12.

Daughter, aged 39, of late F.R.C.S. Has been practically incapacitated for some years by tubercular disease of a large joint but hopes to shortly resume work. Only means of subsistence meanwhile 2*s.* 6*d.* per week from another charity. Relieved five times, £60. Voted £12.

Daughter, aged 62, of late M.R.C.S. Receives a few shillings a week from friends, but is unable to earn anything. Relieved seven times, £78. Voted £12.

Daughter, aged 69, of late M.R.C.S. No income, and dependent on a brother whose means are very small. Has recently undergone a severe operation. Relieved once, £12. Voted £12.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH FOR 1910.

County of Middlesex.—In reporting on the administration of the Midwives Act Dr. C. W. F. Young states that during 1910 as many as 283 midwives notified to the county council that they intended to act as midwives, and that in addition 466 other certified midwives reside in the county. Of the practising midwives only 91 are now enrolled by reason of having been in *bonâ fide* practice before the passing of the Act, the rest being qualified by examination. Dr. Young considers that the county is well supplied with midwives, and that many of them do not attend a large number of cases, though they are anxious to do so. Out of some 27,000 births, it is estimated that 9482 were attended by registered women as midwives and 1356 by nurses under medical men. Medical aid notifications were received in respect of 754 births attended by midwives, a proportion of 2·3 per cent., almost identical with that in 1909. Of 41 cases of puerperal fever notified in the county 15 occurred in the practice of midwives. The report refers to the sanitary regulation of tents, vans, and other moveable dwellings, which frequently give rise to difficulty, as while the local authority can enforce its by-laws (for example, as to obtaining a sufficient supply of water) on the occupant, it cannot do so on the owner of land habitually let as a camping-ground. The principal facts of sanitary administration in the 33 sanitary districts (29 urban and 4 rural) of which Middlesex is now composed are set out in a very instructive manner. Dr. Young's next report should have the further interest of presenting statistical data regarding the several districts which are based on the recent Census enumeration. The population of the administrative county has increased from 792,476 in 1901 to 1,126,694 in 1911.

Metropolitan Borough of Islington.—Islington, one of the largest of the London boroughs, has shared in the diminution of population which has taken place in the more central parts of the metropolis. It had 327,423 inhabitants this year, a decrease of 7568 on the previous Census. Although there is evidence that many dwellings are unoccupied, the density of population is high—117 per acre. There has also been a notable increase in pauperism, an average of 10,476 people per week being in receipt of relief during 1910. The changes in the character of the population, and the possibility that, owing to the system of relief in Islington or to other causes, there is a considerable immigration of persons of the poorest class, give special importance to the efforts of the medical officer of health to deal with unsatisfactory housing, food-supply, and like matters. Several dwellings were closed as unhealthy under the Housing and Town Planning Act during the year, and there is room for a vigorous policy in this respect. Mr. A. E. Harris presses for the appointment of health visitors, not only for the prevention of infant mortality, but in order to deal with individual cases of phthisis notified under the Local Government Board orders. In the absence of visiting these orders merely throw on the health department a mass of comparatively useless clerical work. The report gives details of inspection of kitchens of restaurants, coffee and dining rooms, and similar places, a large number of which were found to be in an extremely unsatisfactory condition as regards cleanliness, lighting, and ventilation. It is an anomaly that while refuse is removed from the large hotels and restaurants, when desired, free of extra charge, there is only a weekly clearance from small coffee-shops and eating-houses; any extra removal is charged for, and the occupiers prefer to keep their bins crowded to their utmost capacity. These small shops are in the poorest parts of the borough, and the accumulated refuse gives rise to various nuisances and breeds large numbers of flies. In places where ice-creams are made the most unsatisfactory condition which is now found on inspection is the want of suitable storage for the materials used, which at present are kept anywhere, and have sometimes been found in the bedrooms of the makers. The inspectors have secured a marked improvement in the cleanliness of milk measures, but Mr. Harris finds that the lids of milk-cans are sometimes in a very uncleanly state. He considers also that the time has come for requiring that foodstuffs, particularly those which are eaten in a raw state, should no longer be sold in open-fronted shops. Mr. Harris has continued the energetic administration of the Sale of Food and Drugs Acts for which Islington has for many years been conspicuous, but he again draws attention to the way in which the clumsy and antiquated provisions of these Acts make it impossible to deal with flagrant cases of misdescription and adulteration, particularly of foods and drinks sold in poor neighbourhoods; and his report contains some striking illustrations of the need for official definitions of foods in this country, comparable to those in force in British colonies and the United States.

County Borough of St. Helens.—Under the St. Helens Corporation Act, 1898, the town council can require any privy ashpit in the borough to be converted and adapted to the water-closet system, whether it give rise to nuisance or not, and any tub or pail-closet to be converted into a water-closet if it creates a nuisance. If the latter do not create nuisance the conversion can still be enforced by the municipality if it is prepared to contribute half the cost. Notwithstanding these provisions a great deal remains to be done in this town to improve methods of excrement and refuse disposal. There remain as many as 2820 privy middens, most of which are in the thickly inhabited portions of the town, and 6382 pail closets, which are still almost as numerous as the water-closets in the borough. The retention of privy-ashpits and the defects in the pail system no doubt contribute to the maintenance of sporadic enteric fever. This disease occurred in 71 houses in 1910 and is understood to be still more prevalent during the present year. Dr. J. J. Buchan gives figures which show that it would be practicable to continue conversion at a much greater rate than hitherto without materially adding to the local rates. In August, 1910, an outbreak of poisoning attributed to canned meat was investigated. A large tin of a well-known brand of corned beef had been opened by a grocer and sold by the slice on the same or the next day to 11 customers, through whom the meat was eaten by 33 persons. All but one of these became ill within a very short time of eating the meat; the shortest period of incubation was two hours and the longest ten hours; the majority were affected in about four hours. The symptoms consisted chiefly of vomiting and severe diarrhœa, continued from six to 24 hours after the onset; the illness was accompanied by a great amount of depression, which left the persons affected ill for some days. Bacteriological examination failed to show any evidence of the presence of bacilli of the Gaertner group or B. botulinus, and the general history of the outbreak made it probable that it was due to bacterial toxin rather than to living bacteria. Dr. Buchan considers that much good has been done by the systematic visiting by a trained nurse of practically all births notified under the Notification of Births Act. In this way the percentage of infants who are breast-fed has increased, and on the present method of reckoning amounted to 98 in 1910. An inquiry into 2170 cases showed that only 6·6 per cent. of the infants originally reckoned as breast-fed at birth were weaned before they were six months old. In St. Helens the town council pay a small fee—6*d.* per birth—to medical practitioners and midwives notifying under the Act.

County Borough of Blackpool.—Dr. E. W. Rees-Jones's report contains several matters of interest. The birth-rate of Blackpool, which was 27·74 in 1898, has now fallen to 16·7; the death-rate for 1910 was as low as 12·47. The Census population, 58,378, on April 1st last is, of course, greatly below the normal population of this popular seaside resort during a large part of the year. Blackpool is so dependent on visitors that there is special need for precautions against the spread of infectious disease through lodging-houses, and Dr. Rees-Jones strongly urges, in regard to phthisis, that the sanitary authority should have compulsory powers to disinfect thoroughly all premises which have been occupied by consumptive persons, and that it should be a penal offence to allow such premises to be occupied by others without previous disinfection. Measles has been a notifiable disease in Blackpool for over 20 years; in 1910 the notifications were 660, and the deaths 4 only. Dr. Rees-Jones considers it doubtful whether the administrative measures based on notification have had much effect in reducing the prevalence of the disease, but believes that a marked effect has been produced by them on the case mortality. The cost of the infectious diseases hospital to the rates, including interest,

sinking fund, renewal expenses, and cost of disinfection, averaged £2 5*s.* per patient per week; cost of maintenance in food averaged for the year 4*s.* 11*d.* per head per week. Special attention is given by the sanitary authority to basement dwellings; 89 families living in basement rooms have only one room for the whole of the family. In Blackpool the administration of the Shop Hours Acts and Employment of Children Act is carried out in the department of the medical officer of health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

County Borough of Stockport.—Mr. H. E. Corbin, in presenting the report of the school medical officer (Dr. M. Gertrude Edis), is able to state that the amount of treatment obtained as a result of inspection is very satisfactory. Of the 5102 children inspected out of a school population of 17,906, 68·6 per cent. were found to have one or more defects, and 15·6 per cent. parents attended. As in most other places, great difficulty exists in dealing with ringworm and verminous conditions, and less improvement is reported in these conditions than in other defects, the actual percentage of verminous heads found being increased over last year's figure. It is suggested that the cloakrooms help in spreading the condition. In connexion with anæmia (379 cases) it is suggested that the badly ventilated classrooms are a contributory factor. There were 32 mentally defective children, and 215 "backward" cases, of whom 60 per cent. were accounted for by some physical defect, and 40 per cent. showed no obvious cause. 126 cases had deformities. Difficulty in the treatment of ringworm arose partly because of the refusal of the infirmary board to treat school cases, and led to the issue of a circular letter to all practitioners in the town and to the passing of special administrative measures. The success of these measures is not stated. A detailed report on the sanitary circumstances of schools reveals a number of grave defects; in four schools privy-middens exist, many schools are dirty, cloakroom accommodation is bad, and in some schools the heating arrangements are very poor, in one department so much so that frequent exercise has had to be added to overcoats worn in the class-room to maintain the temperature. This last school was a non-provided institution.

County of Ayr.—Dr. C. R. Macdonald's report takes us up to July, 1911, and comprises reports for the Northern, Kilmarnock, and Ayr and Carrick districts, and for the schools in the Burgh of Ayr. In the Northern district the number of "entrants" and "leavers" examined was 3537, the number found defective being 2309; out of 280 special cases presented by the teachers, in 273 the attention of parents was drawn to a remediable condition. It is not a little remarkable that for all these children only 122 parents attended, and it would be extremely interesting to have a light thrown on the social school conditions, if any, which go to produce this effect. A large proportion of the defects found among the routine cases were in regard to cleanliness, and when these are subtracted only 997 cases remain, of which 360 were "bad" dental caries, 163 defective vision, and 175 deafness. There were 36 cases of tuberculosis and 18 of valvular disease of the heart. It is curious to note that only one case of enuresis is recorded. The figures quoted are fairly typical of many other districts, and it is a matter for consideration whether an economy in energy might not be effected by a method of examination other than that of mechanical routine. It is also a matter of interest to consider how long an investigation of some kind into the digestive system can be left out of school examinations. Possibly some light might be thrown by such an investigation on "malnutrition." The medical officer of the Northern district reports on the privy-midden, still existing in some schools, as "an absolute abomination." There is no excuse of any kind for the persistence of these insanitary antiquities. Dr. B. C. Stevens reports for the Kilmarnock district that more parents attended than last year, 3654 routine cases were seen and 365 special cases, and with these children 364 parents came to the inspection. One in nine of these children suffered from malnutrition, as compared with the figure of 1 in 18 for the Northern district, and 1 in 23 for the district of Ayr and Carrick. As the three districts concerned are only divided for administrative purposes, and the report does not note any special differences between them, it is to be presumed that these wide divergences are due to differences of standard in estimating nutrition.

Hampshire County Council.—Dr. Robert A. Lyster's report deals with the three districts into which the county is divided for school purposes, containing 42 urban and 308 rural schools, with 13,753 and 33,009 children in average attendance respectively. During the year 1185 visits were made to schools, of which 458 were routine visits, and 48,895 examinations of children made, children known to be defective being examined on several occasions. 7885 routine cases were inspected and 41,010 special examinations made, this figure including re-examinations. The method adopted provides for the registering not only of the usual observations, but also, among other matters, gives the number of rooms in the homes of children and number occupied, and the occupation of the parents. The coöperation of the teachers is greatly encouraged, and went as far in one school as the actual rehearsing of a medical inspection in order to secure smoothness of working. It is interesting to note on these figures that Dr. Lyster classes 1·06 per cent. "entrants" (5 years) as suffering from bad nutrition and 0·89 per cent. "leavers" (13 years); this is a diminution on the figures of the previous year, whereas dirtiness has increased. In regard to clothing Dr. Lyster notes the prevalence of over-clothing, and the fact that this is often confined to the chest and abdomen, the legs being left bare. This is probably a universal experience with certain sections of the population, and may well account for the prevalence of bronchitis and broncho-pneumonia among children whose parents are of the poorer class. Considerable attention is directed to the condition of clothing, as also of footgear, and a strong plea is put in for the "economical and hygienic" clogs. The difference between the North where clogs are habitually worn and the South where they are not appears to be a matter of social custom only. Medical inspection will prove a powerful weapon indeed if it can produce not only fashions which will tend to eradicate pediculi, but also fashions in footwear. The figures for attendance of parents at examination are not given, but it is stated that few attend, partly owing to the long distances to be travelled. Despite this over 54 per cent. obtain treatment for the defects pointed out at inspection, and apart from dental defects 64·4 per cent. are treated. A special investigation was made in the Fareham Poor-law area to discover why children needing treatment had not obtained it. Inquiries were conducted concerning children living in 282 homes, and the fact emerged that more than half these cases had a total income (excluding rent) of not more than 10*s.* to 20*s.* a week, while 10 per cent. of the cases were below 10*s.* a week. A tabulation of special work done in connexion with schools by teacher and others is given, and is interesting as affording a measure of the amount of individual initiative and goodwill available for school purposes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7900 births and 4056 deaths were registered during the week ending Nov. 11th. The annual rate of mortality in these towns, which had been 14 4, 13·3, and 13·5 in the three preceding weeks, declined to 13·1 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 14·1, or 0·1 per 1000 above that recorded in London during the same period. The death rates in the 77 towns last week ranged from 5·0 in Walthamstow, 5·1 in King's Norton, 5·7 in Willesden, and 6·2 in Reading, to 19·0 in Swansea, 20·0 in Stockton-on-Tees, 20·7 in Sunderland, and 21·6 in Bootle. The 4056 deaths from all causes in the 77 towns were 126 fewer than the number returned in the previous week, and included 279 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 301 in the 11 preceding weeks. Of these 279 deaths, 113 resulted from infantile diarrhœa, 55 from diphtheria, 37 from measles, 26 from scarlet fever, 24 from enteric fever, and 24 from whooping-cough, but not one from small-pox. The mean annual death-rate from these epidemic diseases

last week was equal to 0·9 per 1000, against 1·1 and 1·0 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœa, which had steadily decreased from 2714 to 128 in the 11 preceding weeks, further declined to 113 last week, and included 39 in London and its suburban districts, 10 in Manchester, 7 in Liverpool, 6 in Birmingham, and 4 in Sheffield. The deaths referred to diphtheria, which had been 60, 46, and 56 in the three preceding weeks, were 55 last week; 15 deaths occurred in London, 4 in Stoke-on-Trent, 4 in Liverpool, 3 in Portsmouth, and 3 in Southampton. The 37 fatal cases of measles were 1 in excess of the number in the preceding week, and included 11 in London and 4 in Tottenham. The deaths attributed to scarlet fever, which had steadily increased from 10 to 30 in the four preceding weeks, fell last week to 26, and of these 7 were registered in London, 4 in Liverpool, 3 in Stoke-on-Trent, and 2 in Birmingham. The deaths assigned to enteric fever, which had been 48, 28, and 35 in the three preceding weeks, declined last week to 24, of which 3 were recorded in Birmingham, and 2 each in London, Blackburn, York, and Hull. The 24 fatal cases of whooping-cough were equal to the average in the three preceding weeks, and included 8 in London, 3 in St. Helens, and 2 in Coventry. The number of scarlet fever patients in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 2189 in the 10 preceding weeks, had further advanced to 2203 on Saturday last; 292 new cases of this disease were admitted to these hospitals during the week, against 344, 297, and 269 in the three previous weeks. These hospitals also contained on Saturday last 1249 cases of diphtheria, 174 of whooping-cough, 130 of enteric fever, and 83 of measles, but not one of small-pox. The 1108 deaths from all causes in London last week were 32 fewer than the number in the previous week, and included 196 which were referred to diseases of the respiratory system, against 228, 210, and 170 in the three preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 158 and 144 in the two preceding weeks, further declined to 136 last week, and 325 inquest cases were registered. The causes of 39, or 1·0 per cent., of the deaths registered in the 77 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Manchester, Leeds, Bristol, West Ham, Bradford, Nottingham, Stoke-on-Trent, Portsmouth, and in 51 other smaller towns. The 39 uncertified causes of death in the week under notice included 8 in Birmingham, 4 in Bootle, 4 in Warrington, 4 in South Shields, and 3 in Liverpool.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 798 births and 533 deaths were registered during the week ending Nov. 11th. The annual rate of mortality in these towns, which had been 16·7 and 16·4 per 1000 in the two preceding weeks, was equal to 16·3 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 16·1 per 1000, and was 2·0 per 1000 above the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 12·3 and 14·5 in Paisley and Dundee to 18·1 in Edinburgh and 18·9 in Perth. The 533 deaths from all causes were 5 fewer than the number in the previous week, and included 48 which were referred to the principal epidemic diseases, against 52 and 47 in the two preceding weeks; of these 48 deaths, 14 resulted from diphtheria, 13 from measles, 9 from whooping-cough, 9 from diarrhœa, 2 from scarlet fever, 1 from enteric fever, but but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·5 per 1000, and was 0·6 per 1000 above the mean rate from the same diseases in the 77 large English towns. The deaths attributed to diphtheria, which had been 5, 8, and 11 in the three preceding weeks, further rose last week to 14; 8 deaths were recorded in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths assigned to measles, which had steadily increased from 1 to 15 in the six preceding weeks, slightly declined to 13 last week, and included 7 in Aberdeen and 4 in Glasgow. The fatal cases of whooping-cough, which had been 5, 4, and 5 in the three previous weeks, rose to 9 last week, and of these 4 occurred in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The deaths referred to diarrhœal diseases, which had decreased from 41 to 12 in the four preceding weeks, further declined last week to 9, all but one of which were of infants under two years of age; 3 deaths were registered in Glasgow and 2 in Paisley. The deaths attributed to scarlet fever, which had decreased from 8 to 4 in the four preceding weeks, further declined to 2 last week, and were recorded in Dundee and Leith respectively. The fatal case of enteric fever was registered in Leith. The deaths referred to diseases of the respiratory system, which had increased from 78 to 116 in the three previous weeks, declined to 108 in the week under notice, but were 43 above the number in the corresponding week of last year. Of the 533 deaths from all causes in the Scotch towns last week, 155, or 29 per cent., were recorded in public institutions, and 21 deaths were attributed to various forms of violence. The causes of 15, or 2·8 per cent., of the deaths in the eight towns last week were not certified; in the 77 large English towns the proportion of uncertified causes did not exceed 1·0 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 631 births and 388 deaths were registered during the week ending Nov. 11th. The annual rate of mortality in these towns, which had declined from 19·6 to 17·1 in the five preceding weeks, rose to 17·6 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 14·1 per 1000, while in the eight Scotch towns it was equal to 16·1. The annual death-rate last week was equal to 22·1 in Dublin (against 12·8 in London), 15·7 in Belfast, 19·7 in Cork, 15·3 in Londonderry, 8·1 in Limerick, and 15·2 in Waterford; while in the 16 smallest of these Irish towns the annual death-rate did not exceed 13·6 per 1000. The 388 deaths from all causes were 10 in excess of the number in the previous week, and included 33 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 40 in the eight preceding weeks; of these 33 deaths, 10 resulted from diarrhœal diseases, 9 from measles, 6 from diphtheria, 5 from scarlet fever, 2 from whooping-cough, and 1 from enteric fever, but not one from small-pox. These 33 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·5 per 1000; in the 77 English towns the mean death-rate from these diseases did not exceed 0·9 per 1000, while in the eight Scotch towns it was equal to 1·5. The deaths attributed to diarrhœal diseases, which had steadily decreased from 121 to 24 in the eight previous weeks, further declined last week to 10, all but one of which were of infants under two years of age; 5 deaths were recorded in Dublin. The deaths referred to measles, which had increased from 1 to 6 in the four preceding weeks, further rose to 9 last week, and comprised 6 in Dublin, 2 in Newtownards, and 1 in Cork. The six fatal cases of diphtheria were 4 in excess of the average in the four preceding weeks, and comprised 2 each in Dublin, Belfast, and Cork. Of the 5 deaths assigned to scarlet fever, 3 were recorded in Dublin and 2 in Belfast. The 2 fatal cases of whooping-cough and that from enteric fever also occurred in Belfast. The deaths referred to diseases of the respiratory system, which had been 57 and 77 in the two preceding weeks, slightly fell to 75 in the week under notice. Of the 388 deaths from all causes in the Irish towns last week, 117, or 30 per cent., were recorded in public institutions, and 5 were attributed to different forms of violence. The causes of 12, or 3·1 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 1·0 per cent. in the 77 large English towns, and was equal to 2·8 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon: F. A. Capps to Haulbowline Hospital. Staff-Surgeons: H. Huskinson to the *Boadicea;* and E. R. L. Thomas to the *Victory*, additional, for disposal. Surgeon and Agent, Ryde, Isle of Wight: J. W. Pridmore.

In accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Shirley Hall Birt has been allowed to withdraw from His Majesty's Naval Service with a gratuity (dated Sept. 18th, 1911).

ROYAL ARMY MEDICAL CORPS.

Major Albert Pearse retires on retired pay (dated Nov. 15th, 1911).

Lieutenant Benjamin Biggar, from the seconded list, is restored to the establishment (dated Oct. 1st, 1911).

Colonel W. G. A. Bedford, C.M.G., principal medical officer at Hong-Kong, has been selected for appointment as Principal Medical Officer of the London District in succession to Colonel A. Peterkin. Lieutenant-Colonel A. F. Russell, C.M.G., has been appointed Principal Medical Officer in Egypt in succession to Colonel T. M. Corker, who is appointed Principal Medical Officer of the Eighth (Lucknow) Division of the Northern Army in India. Lieutenant-Colonel W. W. Pike, D.S.O., senior medical officer at Cairo, has been selected for appointment as Principal Medical Officer of the Bombay Brigade, vice Colonel R. H. Forman, retired. Lieutenant-Colonel F. H. Treherne has embarked for India to take up the appointment of Principal Medical Officer of the Bangalore and Southern Brigades, vice Colonel H. J. R. Moberly, who has retired. Lieutenant-Colonel H. J. Barratt, senior medical officer of the Straits Settlements, has been appointed Principal Medical Officer of the Allahabad Brigade, relieving Colonel L. E. Anderson, transferred as Principal Medical Officer of the Bareilly, Gharwal, and Dehra Dun Brigades. Lieutenant-Colonel W. H. Starr has taken up charge of the Military Hospital at Lichfield, vice Lieutenant-Colonel G. W. Brazier-Creagh, C.M.G. Lieutenant-Colonel W. A. Morris, commanding the Station Hospital at Allahabad, has been selected for increased rate of pay under Article 317 of the Royal Warrant. Major S. F. Clark has taken up duty as Medical Inspector of Recruits in the Western Command at Headquarters, Chester, in succession to Major G. S. McLoughlin. Major A. O. B. Wroughton, on return to duty from sick leave, has been posted to the Eastern Command. Major H. C. French, specialist in dermatology and venereal diseases at Malta, has arrived home on leave of absence. Major E. W. P. V. Marriott has arrived home from Gibraltar, tour expired. Major E. M. Morphew, lately commanding the Station Hospital at Ranikhet, has been transferred to the Home Establishment and appointed for duty in the Western Command. An exchange of destinations in India has been approved by the Director-General between Major W. T. Mould and Major L. P. More, who are both under orders to embark during the ensuing trooping season. Major J. W. Leake has taken up duty at Sierra Leone. Major G. S. Crawford has been appointed Recruiting Medical Officer at Dublin in succession to Major G. W. Tate, appointed Medical Inspector of Recruits. Major E. P. Sewell, lately serving at Belfast, has taken up duty at Ceylon as Specialist Sanitary Officer. Major G. St. C. Thom, specialist in otology and laryngology, has been granted one year's extension of Indian tour of service. Major F. J. W. Porter, D.S.O., in medical charge of effective troops at Cosham, has been placed under orders for duty with the Northern Army in India. Major R. C. Lewis, on the closing of Carnarvon Camp, has joined for duty at Pembroke Dock. Major H. G. F. Stallard, on relief by Brevet-Colonel R. S. F. Henderson, K.H.P., has been transferred from Army Headquarters, Simla, to Cherat. Major N. Marder, from Cosham, has taken up duty at Portland. Major G. Mansfield, in charge of the Military Hospital at Norwich, has been granted ten days' leave. Captain J. J. O'Keefe has been appointed to hold civil medical charge of Roorke, in addition to his military duty, in succession to Captain B. E. M. Newland, I.M.S. An exchange on the roster for service abroad has been approved by the War Office between Captain M. F. Foulds, specialist in advanced operative surgery at Belfast, and Captain A. F. Carlyon, serving at Devonport. The latter will accordingly take up duty at Mauritius during the ensuing trooping season. Captain P. G. Hyde, from Dublin, has arrived in Ceylon for a tour of service. Captain W. F. Tyndale, C.M.G., has taken up duty as Specialist Sanitary Officer at Devonport on transfer from the Irish Command. Captain R. C. Wilmot has joined for duty at Colchester as Specialist in Ophthalmology on transfer from the Southern Command. Captain W. Byam has arrived home on leave of absence from duty with the Egyptian Army. Captain F. E. Rowan-Robinson, at present serving at Norwich, has been granted leave of absence from Dec. 1st to date of embarkation to Bermuda. Captain H. B. Kelly has been appointed to the medical charge of the Military Families Hospital at the Curragh. Captain M. J. Cromie, Captain E. W. Powell, and Captain A. D. O'Carroll have been detailed for duty on board the troopship s.s. *Plassy*, which left Bombay for Southampton on Nov. 9th. Lieutenant H. S. Ranken has taken up duty in the Egyptian Army with the rank of Bimbashi, for appointment under the Government of the British Sudan.

INDIAN MEDICAL SERVICE.

Surgeon-General H. W. Stevenson has received an extension of his leave of absence home from India. The Lieutenant-Governor of the Punjab has appointed Lieutenant-Colonel C. H. James a first-class Civil Surgeon. Lieutenant-Colonel P. Hehir has taken up duty as Officiating Principal Medical Officer of the Burma Division. Lieutenant-Colonel J. Morwood on return from leave has been appointed Civil Surgeon of Shahjahanpur, United Provinces. The services of Major E. L. Ward, superintendent of the Central Jail at Lahore, have been placed temporarily at the disposal of the Coronation Durbar Committee for employment at Delhi. Major D. N. Anderson has embarked for India on the expiration of his leave of absence. Major E. C. G. Maddock has been permitted to extend his leave of absence from India on the recommendation of a medical board for a further period of six weeks. Captain E. A. Walker, Bengal Presidency, has arrived home on leave of absence. The services of Captain S. B. Mehta, plague medical officer at Rohtak, have been placed at the disposal of the Government of India for employment under the Department of Education in the Punjab. Captain W. J. Fraser, officiating civil surgeon at Chanda, has been placed on deputation for a course of training at the X Ray Institute, Dehra Dun. Captain F. W. Sumner, officiating civil surgeon at Shahjahanpur, has taken up duty at Fategarh, United Provinces, relieving Captain E. P. Mackie, who has been appointed Officiating Civil Surgeon at Bijnar. Captain E. J. C. McDonald, officiating civil surgeon at Sibsagar, has been selected for employment as Medical Officer in Charge of the Military Police Force engaged on active service with the Abor Expedition. Captain J. W. McCoy, Bengal Presidency, has received two months' extension of his leave of absence home from India. Captain T. C. Rutherfoord, civil surgeon of Bilaspur, has been appointed to the medical charge of the Raipur District. Captain H. C. Keates has taken up duty as Superintendent of the Jullundur District Jail. On return from leave Captain A. F. Babonall has been transferred from Ambala District to Gurgaon as Plague Medical Officer. Captain W. E. Brierley has embarked for service in India. Captain W. L. Trafford has received permission to extend his leave home from India for a further nine months.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st London (City of London) Field Ambulance, Royal Army Medical Corps: Lieutanant Eardley L. Holland resigns his commission (dated Nov. 11th, 1911).

1st South Midland Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be captains (dated Oct. 1st, 1911):—Lieutenant Cyril R. Lunn, Lieutenant William M. Sturrock, and Lieutenant William McCall.

2nd South Midland Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be captains (dated Oct. 1st, 1911):—Lieutenant William A. L. Holland, Lieutenant John H. Hobling, and Lieutenant Alfred A. Hingston.

Attached to Units other than Medical Units.—Lieutenant Frederick W. K. Tough to be captain (dated Oct. 1st, 1911).

For Attachment to Units other than Medical Units.—Thomas Charles Hunter to be Lieutenant (dated Sept. 9th,

1911); Oskar Teichmann to be Lieutenant (dated Sept. 16th, 1911); Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel Charles Henry Gwynn, from the 4th Battalion, The King's (Shropshire Light Infantry), to be Lieutenant-Colonel with the honorary rank of Surgeon-Colonel (dated Nov. 11th, 1911).

The undermentioned officers of the Royal Army Medical Corps to be Adjutants of Schools of Instruction:—Captain Hugh Herbert James Fawcett (dated Oct. 19th, 1911), and Captain Farquhar McLennan, Captain Charles Bramhall, Captain Richard Nason Woodley, Captain Charles Reginald Sylvester-Bradley, Captain Richard Brassey Hole, Captain John Martin Maynard Crawford, Captain Montague Frederick Grant, Captain Henry Horace Andrews Emerson, and Captain Roland Harley Bridges (all dated Nov. 1st, 1911).

Deaths in the Services.

Surgeon-Major-General Robert Wyatt Meadows, A.M.S., at his residence, "Fensalir," Saltash, Cornwall, on Nov. 9th, in his 80th year. He entered the army as assistant-surgeon, joined the 9th Norfolk Regiment at Malta in 1854, and, volunteering for war service, was sent to the Crimea. He was present at the battle of Inkerman, and served throughout the whole of the siege of Sevastopol. At the conclusion of the war he was gazetted to the 68th Regiment and proceeded to Canada; later he went to India and rendered excellent service during the cholera epidemic at Mhow, in Central India, and for which he received the special thanks of the Commander-in-Chief (the late Duke of Cambridge). After 20 years' foreign service he came to England in 1874, and was appointed medical officer in charge of Bull Point, Devonport. In 1878 he went to Bengal, being attached to the 60th Rifles, and served during the Afghan war of 1879–80. Later he was selected to be principal medical officer of the 3rd Division, and took part in the march from Kandahar to Cabul, under Sir D. Stewart, and was at the battles of Kheyl and Urzoo, as well as at some minor engagements. At the close of the war he was promoted deputy-surgeon-general to the Mhow Command. He returned to England later and was appointed principal medical officer of the old Western Command at Devonport. He was afterwards made principal medical officer at Gibraltar, and was promoted surgeon-major-general. In 1892 he retired from the service and took up his residence at Saltash.

Close of a Remarkable Career.

News comes from Calcutta of the death of Surgeon-Lieutenant-Colonel K. P. Gupta, I.M.S., at the age of 68. In spite of extreme poverty in early life he had a distinguished student career at the University of Calcutta, and not only supported himself out of scholarships but managed to contribute to the maintenance of his widowed mother in their native village of Bengal. He passed the B.A. examination with distinction in 1865 and obtained first place in the M.A. examination a year later. After passing the final M.B. examination in the first division in 1868 he proceeded to Scotland and qualified as L.R.C.P. & S. within a year. In 1879 he obtained the F.R.C.S. Edin. and in 1884 the D.P.H. of Cambridge. He passed high into the Indian Medical Service and remained in that service for 29 years. He was Deputy Sanitary Commissioner of Bengal for a considerable period and rendered valuable service to the Government. Lieutenant-Colonel Gupta was much beloved by his fellow countrymen and was an active benefactor to his native village.

The Shortage in the Medical Services.

In answer to Mr. Bennett Goldney in the House of Commons on Nov. 13th, Mr. Macnamara said that the shortage of medical officers in the Royal Navy Medical Service at the present time was practically the same as it was 12 months ago—20 had entered and 22 had gone owing to retirements or deaths. The shortage was 60 of all ranks. In reply to a similar question with regard to the Royal Army Medical Corps of all ranks in the Regular Army, in the Reserve, and in the Territorial Force, Mr. Tennant said: The present shortage was as follows:—Regulars: officers, 22; other ranks, 208. Reserves: officers, *nil;* other ranks, 3174. Territorial Force: officers, 283; other ranks, 1759. There is no definite establishment of officers of the Special Reserve, but the present strength amounted to 114. At the last three examinations for commissions the number of candidates qualified exceeded the number of vacancies. For the examination to be held next January for not less than 20 vacancies three candidates had already entered, but the list would not be closed until Jan. 15th.

Indian Medical Service Examination.

An examination for not less than 12 commissions in the Indian Medical Service will be held in London on Monday, Jan. 22nd, 1912, and the five following days. Particulars and the necessary forms for application can be obtained from the Military Secretary, India Office, London, S.W.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—There is no doubt that a large majority of the profession is strongly opposed to the suggestion that the medical benefits under the Insurance Bill—soon to become the Insurance Act—shall be dispensed by "contract" with the doctors at a uniform and continuous *per capita* rate. Among those who assent to this contract system are many who do so only because they regard it as inevitable, or as the only practicable system, and many others who think that all objections to the system pass away if the scale of payment is adequate. There are very few of us who hold that it is in principle as well as in practice the right system of payment of doctors. The simplest and best way to test one's conviction of its merits is to answer the question whether it is adapted for all classes of the community, the rich as well as the poor. The initiation of the system was due to the desire of medical men to extend *their charity* to their poorer neighbours. Is a system founded on voluntary charity adapted for compulsory State assurance? Surely we have never had a more extraordinary proposal to fill old wine-skins with new wine than is this!

You have already, in June last, extended to me the courtesy of your columns to urge my professional brethren to refuse the position offered them under the Insurance Bill, which is, in a word, to underwrite the "medical benefit" of that Bill. I will not repeat what I then said, but will only add that the way in which "free doctoring" has been spoken of by the Chancellor of the Exchequer as one of the great attractions of the Bill to the assured is the clearest proof of the danger of this Bill to the medical profession. Will this "bribe" of "free doctoring" and "no doctors' bills" be paid by the State or wrung from the impoverished pockets of the general practitioner?

The contract system is not essential or inevitable to a scheme of sickness insurance. There are at least three other possible methods; two of these can be dismissed at once—the system of State doctors to attend only the insured and the system under which the State or the Local Insurance Committees would undertake to pay the bills for medical attendance upon the insured. These plans have no advocates, and we need not discuss their drawbacks. The objections which were urged to the latter system by your correspondent, Dr. J. P. Walker, throw a lurid light upon the difficulties of carrying out medical attendance upon insured persons.

The real practicable alternative to the "contract system" is to include the cost of medical benefit in the weekly insurance money and let the insured man use it in the payment of his doctor for services rendered in exactly the same way as he will use the rest of the money in the payment for his other necessaries. It is evident that if the sum paid to the profession under a scheme of "contract" is "adequate" it must equal the total sums that should be paid by the sick members of the insured community under the ordinary method of payment for work done. An "adequate" *per capita* rate must at least equal the "adequate" remuneration of the doctors for the work they do. The sum of money, therefore, that would be required for "payment for work done" would not exceed that paid under an "adequate" contract system. But there would be this difference: the money would be paid directly to those who earn it, and at the time of earning it, and there would be that close and direct association between work and remuneration that sweetens both. The "contract system" lends itself to abuses that "payment for work done" does not. The latter would

prevent—unreasonable demands upon the doctor, and valetudinarianism or malingering. When each visit of the doctor has to be paid for in hard cash the poor man will not be tempted to make undue calls upon his doctor. Undoubtedly one of the chief difficulties in the working of any system of sickness insurance is that of valetudinarianism or malingering. It is openly stated that since the Workmen's Compensation Act came into force injuries have been more slowly recovered from than heretofore. We all have daily evidences of the potent influence of mind over body, and it does not involve any charge of moral obliquity to maintain that the need to earn one's living is a healthy stimulus to convalescence, and that when this stimulus is removed convalescence is apt to be prolonged. If the Insurance Act is not to be an intolerable burden to the State, and a blighting influence upon the wage-earning population, it must leave the sick man with a very direct interest in getting well as quickly as ever he can; and to force him to pay for his "medical benefit" out of his insurance money will be a simple and efficient means of applying the pressure which will be the necessary stimulus.

Among other advantages of the "payment for work done" system are these: There is no need for a wage-limit, as the scale of fees would vary, as at present, in accordance with the financial ability of the patient; the question of the control of doctors by Local Insurance Committees or by societies and clubs would not arise; the payment for consultations, operations, and the services of specialists of all kinds, as well as the payment for hospital treatment, can be arranged quite easily and along the same lines as the payment of the regular doctor.

Were this system to be adopted the doctors would have to contribute to its working by giving a certificate to enable the sick man to receive each week's insurance money, such certificate stating that the insured man was duly carrying out his doctor's advice and was still unfit for work, and it might include a statement of the number of medical visits paid during the week and the amount of the fees that had been paid to the doctor for his attendance. The doctors would also have to accept small cash fees and to insist on their payment at the time.

I must not encroach further upon your valuable space, and in conclusion would only urge all my professional brethren to realise that the "contract system" is not indispensable to the insurance scheme, that the ordinary mode of conducting medical practice—payment of fees for work done—is easily adapted to the insurance scheme, and I cannot help thinking that its adoption is essential to the honourable conduct of the profession of medicine and to the safeguarding of the industrial community from evils inherent in "contract practice."

I am, Sir, yours faithfully,

Nov. 14th, 1911. ALFRED PEARCE GOULD.

To the Editor of THE LANCET.

SIR,—In the letter which you kindly published on Nov. 4th I put forward briefly my reasons for believing that a *per capita* system of payment will, if the premium is adequate, be advantageous to medical men. If it is true to say "that silence gives consent," then it is fair to conclude that my arguments are either unanswerable, inasmuch as no opponent has come forward to refute them, or that no opponent read my letter. I should like, with your permission, to add a few further considerations in support of my contention.

In my letter of Nov. 4th I referred to the fact that a considerable percentage of medical men is now, and has been for generations, working on the contract system in which payment is by salary. Surely everything that can be said against the *per capita* system applies to this system of payment by salary—that is to say, it is "immoral, dishonest, inherently and ineradically bad and inquisitorial." One must suppose that the writers who have flung these epithets understand what they meant. Is it too much to ask them to tell us on what grounds, in what sense, aspect, or respect, they consider those qualities applicable to the *per capita* system? I have nowhere yet seen any clear statement of the case against contract practice, and if one of those who oppose it will kindly put forward his points without relying too much upon adjectives of vague or undefinable meaning I for one should be greatly enlightened. At present I know of no valid objection to the *per capita* system when worked on an adequate premium. If the premium is inadequate no abuse of the system can be too strong. If the premium is adequate—and of course "adequacy" is a word of elastic meaning—it has the strange property of denoting one thing for a "society member," sound and well on joining, and another thing for a mere "Post Office" individual. I maintain that contract practice is more lucrative than private practice. It seems to me that it is the size of the premium that decides the question of morality or immorality. A premium of 3*s*. 6*d*., or, indeed, anything under the Post Office rate, is, and would be, immoral, and the higher the rate mounts so is immorality gradually shed until we reach the position of the doctor who is paid a yearly fee of £1000 a year for "looking after" his millionaire—work or no work—and we have arrived at what can only be described as a condition of perfect holiness and bliss. The writer who asks, "who but a lunatic could expect a doctor to give attendance and medicine for a year for the price of a pair of gloves or a dozen collars?" is evidently under the impression that all insured persons are and will be ill all the time; he apparently thinks that "*per capita*" means "per sick person" instead of per "insured person." It is obvious he did not read my letter of Nov. 4th in which it was shown that the total receipts in my practice from contract work were equal to the whole receipts from a *larger* number of private *clients* (not patients mind).

I should like to say a word or two in supplement of my remarks, previously published, on the system of "payment by fee," or, as some express it, for "work done," terms which mean generally of course "visit" or "consultation." Supporters of this system appear to be under the impression that there is something definite, precise, something even moral and blessed, in this phrase "work done." Those who contend for payment for "work done" under the Act intend, I presume, that there should be paid us a fixed fee for every "visit." Now what could be more indefinite than this thing "visit"? Does it in any way whatever show value of service rendered? Is there any real connexion between service rendered and fee received? Is there, can there be, any standard of value in this system of payment? Compare a visit four miles away on a bleak evening in January to one in June, or attendance on an anxious case to a call on a trivial one. The fee in each instance is the same! It is obvious when we come to think of it that the relation of fee to "work done" varies within the widest limits. One really "contracts" to "see" patients at so much a visit no matter what the case, no matter what the weather, no matter what time is taken up in earning the fee. I maintain that in its essence private practice is contract work—we "see" patients at so much per "visit" or "consultation." Is it customary to increase the fee if the "visit" is prolonged, involving extra skill or care or anxiety? or to reduce the fee if the conditions of the visit are exactly opposite?

Thus the value of the service rendered has no limit in its variation to the fixed fee. In the same way one can see that though the fee is in some occult way supposed to bear relation to the income, or rather rent of the patient, the relation is anything but regular—so irregular, in fact, that it is foolish to call it "relation" at all. A labourer pays a fee of 2*s*. 6*d*. a visit (the amount of his day's pay) and a person with a hundred times the income pays, we will say, 10*s*. 6*d*. Such a system is indeed farcical in its inequality, its injustice. Perhaps one could say that if there is anyone in the profession who can claim that he works on a system of "payment for work done" it is the surgeon. Fifty guineas, we will suppose, is his fee for an operation for appendicitis. Are any two of his cases alike? I remember a surgeon being called in to remove an ovary which was supposed to be cystic; it was ascertained beforehand that his fee would be 100 guineas. The ovary was found to be cancerous and irremoveable, but there was no offer on his part to reduce the fee. A fee is a fee! I think it is obvious, then, that my contention is fair and cogent, that under our present system of "payment by fee" or for "work done" there is a complete absence of uniformity; that the relation of service rendered to fee received is a value that varies indefinitely. There is no science in the system, to say the least of it.

Now under the *per capita* system the relation—of visit to fee—is absolutely scientific, and in a series of years would be invariable, or nearly so. We can foretell how many births there will be during the year in the whole community, how many deaths, how many cases of illness, how many

accidents. In a district or a corporation area these calculations are also available. I do not say, of course, that I can foretell how many visits I shall have to pay in the next month, but if I took the trouble to count up visits paid in the corresponding months of the last ten years I could get near an accurate estimate. On a *per capita* system, one may say, then, that one will be paid a sum known beforehand (practically a salary) for attending a mathematically calculated and nearly certain number of visits next month. And one has only to do a little sum in arithmetic to find out, if he likes to know, how much he will be paid for every visit he is going to pay next month! This sum or salary is fixed, but the "fee" per visit will vary (if the period for which the calculations have been made is long enough, say 10 years) only with the premium per person insured.

If the premium is, let us say, 8*s*. per head, one will find that for every visit he has paid to his contract *patients* the fee will work out at 2*s*. 6*d*. Next year might be a bad influenza year, and the result might be a paltry 2*s*. 5½*d*.; year after, and so on, there would be slight fluctuations, but over a decennial period we should find an average, probably, of 2·569 shillings as the actual money received for every visit paid during any year. Though the rate is thus found to be slightly wobbly, the same cannot be said of the total sum or salary received. This has been steady, regular, punctually paid without any baneful accompaniment of ledger, day-book, cash book, bill, receipts, letters, bad debts, and other paraphernalia inseparable from a practice worked on a system of "payment for work done."

In my early days I held a small practice in which there was one small club. My monthly receipts were most uncertain, most inconveniently variable, and it required great carefulness to keep our household finances anything like straight. I felt this inconvenience all the more as I had left a salaried post. It was a friend of mine, similarly engaged in country practice, who first convinced me of the advantages of a surgery club. He pointed out the absurdity of sending a bill to a labourer; that the labourer could easily pay 6*s* a year to the surgery club, and that with bad debts and other considerations I should find his plan more lucrative to myself and better for my working-class patients. Since then I have done everything I can to encourage this class of "client" to "insure for doctors' attendance," and after 20 years' experience of this system I am more than ever convinced of its advantages to both parties. I should like to extend it to all classes of my *clientèle*, and I should rejoice if all my practice could be worked on a contract, *per capita*, or whatever one calls the plan or system. To be "busy" brings joy to the half of me that is private practitioner and sorrow to the half that is club doctor; if I was all "club doctor" I could smile when other people smile and weep when they weep. To pass three or four days without seeing a single patient—as happens now and again in the summer—only produces a sort of feeling that is neither one thing nor the other; I am half-hearted whether I weep or chortle in my joy. If I was entirely a "private practitioner" I should never be laughing when other people laughed or crying when they cried, so there is no real enjoyment either way. If I was a club doctor pure and simple I could join in at any time whether the folks are laughing or crying.

I am, Sir, yours faithfully,

West Mersea, Colchester, Nov. 13th, 1911. B. HALL, M.B.

To the Editor of THE LANCET.

SIR,—Many of your readers will be surprised at the letter of Dr. B. Hall, a correspondent who is opposed to "any system of payment by fee" for medical services. It would be interesting to know how many of our brethren share the views of this radical reformer, who utterly condemns what has been the almost universal system of remuneration in our profession throughout the world in the past and present, whatever it may be in the future.

It is true a variety of reasons are given for this novel view. The first would seem to be Dr. Hall's own experience of contract, as compared with private, practice. That experience is no doubt interesting, but in the absence of any definite knowledge of the kind of private practice referred to, its cogency is not great in helping to decide on the respective merits of contract and private practice generally. It is not denied there may be forms of private practice worse than contract. The argument as to "worry" involved in the two classes of practice seems to me rather unsafe, if the public good is the chief desideratum. If the doctor takes the same care of, and interest in, his contract patients as he must do in the case of his private, his worry and anxiety might be expected to be rather more, seeing that he must attend a much larger number to gain the same income as in private practice—that is, at any capitation rate he is at all likely to get. If, because he is sure of his income, and that the capitation fees are bound to come in, he gives more or less perfunctory attendance, then his "worry" might be considerably less; but I feel sure Dr. Hall does not mean to suggest this. The argument that as medical work, owing to various agencies, is likely to get much scarcer in the future, we should therefore be glad to take *per capita* fees, is not a little attractive. Does Dr. Hall mean that as payment for work done must necessarily diminish in the future, it is wise of us to look out for payment for work we do not do?

Why the *per capita* system has been denounced as "immoral," I think, we most of us know very well. It does not mean that it is necessarily immoral, but that it far more easily lends itself to the "immoral" than private practice. Dr. Hall speaks of the "dread of making too many visits" in private practice. Is there no fear of making too few in contract practice? It might be a nice point to decide which was the more "immoral," though the patient might suffer more through the latter.

There can be no doubt that good and honourable work can be done under either system, and I think a majority of us would be found to admit that contract practice under certain circumstances is a necessity. But that is quite another thing from approving of the medical proposals in this Bill. They are most degrading to the profession; they revolutionise it in a way that has never been accomplished by the Government of any civilised country. In Germany there is a £2 a week income limit, but there is every reason for believing that the German profession cordially detests its medical insurance system in spite of it.

Unless the medical practitioners of the country stand firm—and the critical time is close at hand—the chains of contract practice will be rivetted on us too strongly to hold out any chance of breaking them. That individual divisions throughout the country will be able to enforce any income limit locally they may desire is to my mind a pleasant dream, and how it can be regarded in any sense as an equitable compromise for the statutory income limit demanded is to me quite incomprehensible. Our only hope is that the profession by a large majority will refuse to accept any appointments under the Bill when it becomes law. We have already practically pledged ourselves to this, for any pretence that the six cardinal points of the British Medical Association have been conceded is a delusion and a mockery.

I am, Sir, yours faithfully,

Nov. 11th, 1911. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—The time is rapidly approaching when the Insurance Bill will become law, and, in my opinion, it is a matter of very grave doubt whether the interests of the medical profession have yet been safeguarded in the way it has so wholeheartedly demanded.

We placed our case in the hands of the British Medical Association, and we recognise that it has obtained for us two substantial concessions—namely, the administration of medical benefit by the Local Health Committees, and the free choice of doctor by patient. Further, we have been promised adequate representation upon the controlling bodies, and the formation of Local Medical Committees. Nevertheless, the matter which affects us most closely and personally appears to have been seriously neglected. I refer to the amount of remuneration we are to receive for our services.

When the Bill was first introduced we were told by the Chancellor of the Exchequer that financial provision had been made for the payment of a capitation fee of 6*s*., of which a portion (at first said to be 2*s*.) was to go to the chemists. This figure has not been discussed in Parliament, and there has been no promise to increase the lump sum (£4,200,000) allocated for the purpose. Once the Bill becomes law the capitation grant must remain at 6*s*.

It is understood that the policy of the British Medical Association is to leave the matter of the financial arrangements to be fought out in each locality between the local

medical men and the Local Health Committee when the Act comes into operation. But it will then be too late to get anything altered, and both the Local Health Committee and Medical Committee will be absolutely tied by the terms of the Bill and by the financial provisions made. It is *now* that we should secure both adequate remuneration and reasonable terms of service.

We have supported the demand of the Association for an income limit, and have obtained a partial concession on this point. But surely the question of an income limit is indissolubly bound up with that of a capitation fee. The higher the capitation fee, the higher the income limit we are prepared to accept. Suppose, for example, the capitation fee was 20*s*., would anyone who has made the smallest analysis of the figures wish to exclude persons with incomes of £500 or even £1000 a year? It is quite certain that we do not get £1 per head per annum from the whole middle class, taking ill and well together. And so with the income of £2 per week for which we have been agitating. It may be to our advantage, but it is pure surmise that the people of this class are paying, at present, on the average, more than 6*s*. per head per annum for medical attendance. By urging their exclusion we may be cutting our own throats. No figures of any value on this matter have been published, and many of the statements as to approaching ruin made in the medical press will not bear the smallest investigation. The mistake, for example, has frequently been made of arguing from the actual number of patients on the books, when what has to borne in mind is that each doctor will have a share of the insured persons, well and ill, and that he will receive the capitation grant from a number of persons who may be years without once consulting him. The sooner we have some authoritative information, so that we may know what to ask for, the better.

As for the income limit, it is an impossible thing to put it into practice. How are we to find out the incomes of 15,000,000 working people? The machinery to do so would cost another 6*s*. per head. A man works for one employer for £2 a week, is out of work for three weeks, and gets a job at 30*s*. His wife earns 12*s*. at a laundry, a boy gets 7*s*. on a milk-round, and a daughter, as much, or more, in a shop. Moreover, these figures are always fluctuating. To make an approximate estimate of such a man's income would necessitate a Somerset House in every village.

My strong impression is that had we held out from the beginning for an increase of the capitation fee to 7*s*. 6*d*., or a clear 6*s*., with special fees for operations, night visits, and mileage, we should have done more for ourselves than all the concessions obtained up to the present will do. 7*s*. 6*d*. could, and in all probability would, have been granted by the Chancellor. There would have been a single fight, and we should have won. Now there must be a hundred fights all over the country. We have no solid figures upon which to base our demands, and if we be told later on by the Health Committees that any particular point cannot legally be granted, we will have no ground for objection, seeing that we are now tamely accepting the provisions made.

I am, Sir, yours faithfully,

Enfield, Nov. 14th, 1911. R. HALDANE COOK.

To the Editor of THE LANCET.

SIR,—May I be permitted to express my thorough concurrence with your leading article in to-day's issue of THE LANCET. The fondness of some members of our profession for contract work at capitation fees passes my comprehension. How can a system of strictly limited payments for an unlimited amount of work possibly be satisfactory? Does not every man who can afford it get rid of his contract work as soon as ever he can? The refusal of Parliament to adopt the £2 a week wage limit I regard as a blessing in disguise, as it allows the profession to reconsider the question and to adopt what I believe to be the better plan of payment by fee for work done. Is such a system impossible? I think not. The National Deposit Friendly Society has shown that with proper supervision it is perfectly feasible to attend the working classes at a reasonable scale of fees.

Now, under the Bill there are two classes of the insured—viz., the members of approved societies and the Post Office contributors. The former will be amenable to the rules of their societies and under the constant supervision of their visitors and officials. These I would treat at National Deposit Friendly Society rates. This system would be a powerful inducement to economy and a check on malingering, as it would be to the interest of every member of the societies to restrict sickness and thus diminish the doctor's and chemist's bills. The Post Office contributors would have to be separately considered. They will apparently be quite unorganised and without any system of supervision, consequently I believe it will be inevitable to accept them at a capitation fee, which, considering the class of life they will be, should be a pretty high one. Happily this class will be a diminishing quantity. The Bill offers the insured every inducement to join an approved society, and as young good lives come on they will be absorbed by them.

For both classes a properly thought-out scale of extras should be drawn up, comprising night work, midwifery, vaccinations, lunacy certificates, general anæsthesia, surgical operations, and the treatment of fractures and dislocations based upon the scale allowed by the Poor-law. Such briefly is the scheme I advocate which I have submitted to the authorities of the British Medical Association in greater detail. Its advantages, I submit, are as follows: (1) It provides adequate remuneration for work done, and the rate of payment is about the same as large numbers of the insured have been accustomed to pay as private patients, thus preserving private practice among the working class; (2) it obviates the injustice of our being obliged to treat, at a capitation fee, all the insured for disease the result of their own misconduct; (3) it allows for payment for the treatment of the insured in institutions if the profession wishes it; (4) it overcomes the income limit difficulty; (5) it gives the doctor a more direct interest in his patient and gives the insured the satisfaction of feeling that they are treated as private patients.

Consideration for your space forbids me to go into the matter at greater length. I will only plead for unity and a pretty general agreement as to the system to be adopted. The profession, even now, does not seem to realise its power, and there is no doubt that we can obtain fair treatment provided that our demands are logical, reasonable, and just.

I am, Sir, yours faithfully,

HUMPHRY J. WHEELER, M.D. Durh.

High Wycombe, Nov. 11th, 1911.

To the Editor of THE LANCET.

SIR,—I desire to lay before the profession a proposition which is not intended to be antagonistic to the work done by our leaders but rather an addition to it. I think it will be seen that the point I wish to make seems in danger of being overlooked, for the fighting so far has been on the question of control, but I think we ought now, if not already too late, to ask, and with no uncertain voice, the following questions: 1. What will be required of us under the Act? 2. What are we to be paid for it?

My reasons for these questions are as follows: 1. Contracts vary in different parts of the country; in some parts of the Midlands a sum of 1*s*. per lunar month is deducted from the earnings of all adult colliery employees and this pays for all medical and surgical attendance on the employee and, where he is married, on his wife and children under 16 years of age, but does not include midwifery, which is paid for extra at 10*s*. 6*d*. per case. In the valleys of South Wales a system of poundage is in vogue, and sums of 2*d*., or in some cases 3*d*., are deducted from every 20*s*. earned by colliery employees, and these sums pay for all attendance, including midwifery. The ordinary Friendly Society benefit is too well known to require description. What will the benefit be under the Act? and (2) What shall we be paid for it?

This question must be divided into (*a*) By whom will it be paid and (*b*) To whom will it be paid? As to the main question, we are told that we must wait and bargain with Local Insurance Committees. As to this, I say, Heaven alone can help the profession if we do not make our stand now. At present our paymasters are our private patients and contract employers, be they Poor-law bodies, collieries, works, Friendly Societies, or the like. Who will they be in the future? Under the Act we in working-class practices will have no private patients after two or three years, when the benefits have been extended to women and children, and under the Harmsworth amendment we shall have just as many contract employers.

To whom is the money to be paid? At present we receive the whole of the contract earnings and supply the whole benefit, including drugs. In the future drugs and the doctor are to be divorced. Let me show how this will work under a *per capita* arrangement. It is necessary to understand that a certain sum per head will be allowed, and this sum, whether it be 2*s*., or 20*s*., or the figure of 6*s*. alleged to have been used by Mr. Lloyd George, will have to cover the entire cost of the medical benefit—viz., attendance and medicine. Now, taking an ordinary medical case, what will happen is this: The doctor is called in, and he will diagnose the disease, give clinical advice, and write a prescription. The prescription will be taken to a chemist, who has already bargained that he shall be paid for his drugs with an additional 1*d*. or 2*d*. per bottle for his work of dispensing. This part of the medical benefit—i e., the supply of drugs—becomes an unknown quantity so far as cost is concerned and may depend in great measure on economical prescribing. Let us assume that the sum of 6*s*. per annum *per capita* has been fixed (and here let me repeat that whether it is 6*s*. or 16*s*. does not affect the principle of my contention), then in a working-class practice of 2000 men, women, and children we may in the first year of the Act assume that there will be 400 insured persons, of whom 50 will come under the doctor's care and require two bottles of medicine each. Allow that the chemist charges 1*s*. per bottle for drugs and 2*d*. for dispensing, there will be a chemist's bill of £5 16*s*. 8*d*., to be paid out of a total of £120, leaving £114 3*s*. 4*d*. for the doctor. This refers to a normal year, but take such a season as 1888–89 then 200 will be under the doctor, requiring six bottles of medicine each. The chemist's bill will then be £70 and £50 left for the doctor, who will have done 12 times as much work as in the normal year. Surely this is absurd and yet it is what is proposed.

Even admitting that the British Medical Association in 1905 did issue a report saying that some form of contract practice is inevitable, and allowing that, so far as the principle is concerned, their hands are tied, their report would not be stultified if they declined to proceed in this matter until satisfactory pecuniary arrangements have been made. I am, Sir, yours faithfully,

ROBERT J. FARMAN, L.M.S.S.A.

Upper Kennington-lane, S.E., Nov. 12th, 1911.

To the Editor of THE LANCET.

SIR,—The bulk of the correspondence on the Insurance Bill is devoted to the questions of the income limit, the method of remuneration, and the abolition of contract practice. May I point out that these matters are intimately bound up with the question of the Addison and the Harmsworth amendments. The Medical Secretary of the British Medical Association assured us recently that the two former would not be stated in the Bill, but that the Association would see that they were equitably settled by local option through the Medical Committees acting under the Addison amendment; but he warned us that there was a long and strenuous fight before us over this matter. Why should we be obliged to fight for our just dues at all? Mr. Smith Whitaker spoke at Hampstead of the need for "the deletion or profound modification of the Harmsworth amendment," but what of the Addison amendment? The Chancellor of the Exchequer has been telling deputations of various persons who will be the insured that under it they have the power to combine and do anything they like. The Harmsworth amendment provides only for "persons who are receiving medical attendance and treatment under any system, or through any organisation existing at the time of the passing of the Act and approved by the Local Health Committee and the Insurance Commissioners." The Addison goes very much further than this: it provides that "(3) the regulations made by the Insurance Commissioners shall authorise the Local Health Committee by which medical benefit is administered, to *require* any persons whose income *exceeds* a limit to be fixed by them, and to *allow* any other persons" (the italics are mine) to contract out of the Bill and "make their own arrangements for receiving medical attendance and treatment," and the Committee shall pay over "for such persons sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended," and, as the Chancellor points out, they can combine and do what they like with them. There is not one word in the amendment to prevent their starting medical institutes or other contract practice at sweating rates. There is not one word to prevent a claim on the bills of a cancer quack, a herbalist, or a professor of Christian Science. There is no mention of the necessity of associations being approved here; there is no indication that the "other arrangements" need be for *legitimate* "medical attendance" at all. This is no chimera; the matter has arisen as one of the difficulties of the German scheme already; and the Medical Secretary told me after the Peckham meeting that the matter was being considered here. May I urge my fellow practitioners to give this matter urgent consideration, with a view to definite instructions being given to our representatives to have the clause so altered in the report stage as to be safe. If we do not, the income limit is worth nothing, for all above must, and all below may contract out, and will be enabled to organise some contract scheme which, while legal under the Bill, will nullify any advantages we may have gained. I am, Sir, yours faithfully,

Catford, S.E., Nov. 11th, 1911. THORNTON COMBER.

To the Editor of THE LANCET.

SIR,—I am instructed to forward you a copy of the following resolution passed unanimously at a meeting of the Broughton Medical Union held on Thursday, the 9th inst.:—

That the Broughton Medical Union reaffirms its unwavering adherence to the declared policy of the British Medical Association, including the six cardinal points of that policy, in relation to the National Insurance Bill; declines to accept any amendments that would defeat the objects of that policy; and is resolved to refuse any arrangements for medical attendance and treatment which do not comply with that policy.

I am, Sir, yours faithfully,

R. B. FLETCHER,

Manchester, Nov. 11th, 1911. Honorary Secretary.

THE STRIKE AND THE DEATH-RATE IN LIVERPOOL.

To the Editor of THE LANCET.

SIR,—The admirably expressed views of your Special Sanitary Commissioner on the subject of social reform and the necessity of an adequate living wage in order that men may live wholesome lives, so delight me that I can forgive him for the perverse fatality with which he unintentionally misrepresents my arguments. My reputation both in Liverpool and before the profession stands, however, so much at stake that I must reply to parts of his letter and correct misunderstandings.

There is no one keener than I am on the maintenance and increase of sanitary service in our cities, nor less inclined to condone any want of public spirit in any grade of life which may interrupt sanitation and subject a community to the inroads of a plague of infectious disease. But I did think we might have discussed a specific scientific problem and garnered its practical lessons as to modes of propagation of one of the direst of diseases without becoming opportunists and attempting to preach political sermons on inadequate texts.

Let me adduce one argument more to clear my reputation as a lover of sanitary science before coming to the narrower specific issue before us. While I hold that no disease broke out or was actually increased by the interference of the strike with sanitary work, I equally hold that such an effect might have been produced, especially if the strike had been more prolonged. With this in my mind, in my first letter to the *Liverpool Daily Post and Mercury*, I suggested that to prevent the possibility of any recurrence in a future strike of interference with sanitary service some terms should be arranged beforehand with labour leaders as to what was to be contraband of war and what not. The problem for municipalities is just the same as for the railway companies, and the policy of pretending to ignore the existence of trades-unionism when there are millions of workmen enrolled throughout the country is, to my mind, identical with the policy of the ostrich. Last August the city authorities had all the power of the police and military behind them, and yet an alderman wrote to the local press explaining that they were unable to get coal in sufficient quantity to their municipal sterilised milk depôts to prepare the milk

for infants, hundreds of whom would in consequence lose their lives unless the strike came to an end. In his letter your Commissioner informs us that the authorities were unable to swill out the slum courts with a fire hose. One cannot help wondering what would have happened had a great fire broken out.

Making all allowances for slight exaggerations, I do not in the least degree condone any of these interferences on the part of the strikers, but surely our action as sensible and thinking people ought to be directed towards preventing their recurrence. We shall never attain this object by crying out in parrot-like fashion: "Down with strikes, repress the strikers, and give them a whiff of grape-shot if necessary," as one London paper suggested. It is of no avail to shake the mailed first of law and order at the workmen, the vast majority of whom are just as strongly in favour *at present* of constitutional action as those who are opposed to them. There is a social disease to be studied, remedied, and prevented, and those who urge the neglect of that study are only hastening our whole social fabric onwards towards destruction by syndicalism, anarchy, and revolution, followed by the inevitable reaction.

Now as to the narrower problem of infantile diarrhœa and the Liverpool portion of the strike, in the first place my opponent ignores dates and my contention based thereon, that the only period when the strike could have caused an effect was on the decline of the disease incidence, where there is no slightest perturbation to show its influence. I would reiterate that an effect cannot precede its cause. Secondly, my adversary accuses me of dealing exclusively with garbage, and then makes a quotation from one of my letters which does not apply to the point in the least. The same arguments apply as to human excreta left in the slum courts by failure of washing down as for garbage. The interruption occurred in the third week in August and the first infant deaths attributable thereto would be in the fourth week in August or first in September, when the epidemic was declining and nothing in the figures shows an influence of the strike. The same remark applies to interrupted health visits. Again, as to the quotation from me regarding the epidemic being uninfluenced by the strike indicating that infection is probably carried from human dejecta and not from garbage. The human dejecta in question mean, of course, dejecta from other infants infected with the epidemic diarrhœa, and not human dejecta in general, such as accumulated for a few days in the courts. The strike did not increase the number of children ill with the disease, hence amount of infection was not increased in spite of the condition of the streets and courts, and the epidemic ran a quite normal course. Thus the use of my own quotations against me, while ingenious, does not appear to me to be quite so ingenuous, and I trust my opponent now sees my line of argument.

The same applies to my comparison of Dublin and Liverpool. It is not a question of which city displays a greater or less degree of perfection in its sanitary arrangements, nor which city experienced the more severe epidemic, but a comparison of the forms of incidence—rise, maximum, and abatement—in the two cities in the months of July, August, and September, one city at a certain period having its sanitation interrupted by a strike while the other did not. It is an attempt on what I regard as scientific lines to get as near as possible to the question of whether the strike produced any effect, and in my opinion the answer is emphatically in the negative. I am surprised at this point being misunderstood.

But if my opponent desires figures as to actual severity, although they do not bear directly on the case, these figures can now be given. Since then the Registrar-General's figures as to deaths from infantile diarrhœa in the big cities of England and Wales have come in, and Liverpool, although the centre of the strike, does not figure so badly, taking into account that it is always somewhere near the top of the list in severe epidemic years. I have calculated for the 48 cities having over 90,000 inhabitants, the number of deaths during the third quarter of this year per 100,000 inhabitants from epidemic diarrhœa. The 12 cities most severely hit are as follows: Stoke-on-Trent, 217; Burnley, 186; Rhondda, 186; St. Helens, 182; Hull, 171; Bolton, 166; Liverpool, 161; West Ham, 153; Stockport, 152; Walsall, 148; Birmingham, 136; Birkenhead, 136. The average for these 12 cities is 168, which is considerably above the figure for Liverpool.

Your Commissioner now admits that "it is difficult to say how far the increased death-rate was due to the high temperature or to the disorganisation of the sanitary service." I take it, therefore, that he now no longer adheres to his former statement that in two of the weeks in August one-third of the deaths were due to the strike. But he still impugns me for stating that there is no proof "that the preventive efforts in the last two or three years possess any causal relationship with the decrease previous to this summer or that the strike was connected with this summer's increase," and goes on to accuse me of inviting belief that sanitary measures can do no good.

Never was there a more palpable *non sequitur* to a quotation entirely warped from its setting. The two or three summers in question were cold and wet, and the amount of epidemic diarrhœa was greatly reduced everywhere; my point was that there existed no proof that the fall in death-rate in Liverpool differed from the fall in all the rest of the country. Scientific criticism is wanted for any new method, and my mind is so constituted that I cannot attribute a given result to one of two causes working together when elsewhere the same result follows the action of the other cause working alone which for some reason is ignored by the experimenter.

In other words, the character of the summer for me explains sufficiently the falling off in death-rates in previous summers and the increase this summer, in Liverpool as elsewhere. This I express in a negative way by saying that "there is not a shred of proof that the preventive efforts in the last two or three years possess any causal relationship with the decrease previous to this summer, or that the strike was connected with this summer's increase." Yet I am just as anxious as your Commissioner that these preventive efforts should be continued, and increased, and added to, in order that they may be thoroughly tested, and in the end we may find the cause and cure of the disease so that sanitary science may flourish and abound.

I am, Sir, yours faithfully,

Liverpool, Nov. 13th, 1911. BENJAMIN MOORE.

THE ETIOLOGY OF ENDEMIC GOITRE AND CRETINISM.

To the Editor of THE LANCET.

SIR,—Your editorial remarks upon the above subject recall to my memory a series of investigations which I made into the etiology of endemic goitre when I was residing in Lanarkshire in 1898. The results which I then obtained led me almost to the same conclusions as those at which Captain McCarrison has more recently arrived—viz., that the enlargement of the thyroid is due to hypertrophy, and is instituted for the purpose of neutralising a toxin formed by a virus introduced into the organism in drinking water. The reasons for my conclusions were embodied in a paper read before the Glasgow Medico-Chirurgical Society, and published in the *Glasgow Medical Journal* of February, 1899. They were as follows: 1. That the pathological changes met with in the thyroid gland of endemic goitre, prior to the onset of secondary degenerations, are those of simple hypertrophy of the glandular secreting elements. 2. That the absence of general constitutional symptoms in simple goitre obviously indicates that the excess of gland secretion produced by the hypertrophy is neutralised in the body—presumably by a toxin. 3. That many of the characteristics of the endemic disease indicate that drinking water is the agent which conveys the poison; and as the water can be rendered harmless by boiling it is reasonable to suppose that the poison is a *contagium vivum*.

Finally, it is clear that the reduction in the size of the goitre brought about by the administration of thyroid gland substance by the mouth also strongly supports the theory of toxin hypertrophy.

With regard to cretinism, in which there is, of course, a profound constitutional disturbance, we may assume that in that condition the total amount of thyroid secretion formed is neutralised or destroyed by the poison. The result will be an organism in which the thyroid secretion is deficient or absent, and so cretinism will be brought about.

Such, briefly, are the chief reasons upon which the theory of the living virus can be based. Moreover, an examination of the general features of the endemic disease supplies us with a number of facts which are more easily

explained by this theory than by any other that has hitherto been put forward.—I am, Sir, yours faithfully,

Brook-street, W., Nov. 10th, 1911. DAN MCKENZIE.

OLD AND NEW VIEWS ON THE TREATMENT OF CONSUMPTION.

To the Editor of THE LANCET.

SIR,—I hope Dr. Claude Lillingston will forgive me saying that through taking too narrow a view of the sense of the word *fatal* in his letter in THE LANCET of Nov. 11th, p. 1364, he appears unjustly to charge Dr. C. Theodore Williams with being inconsistent. He says: "Dr. Williams writes of acute cases of phthisis that they 'all pass through an early stage to a fatal issue.' Further on he writes: 'It is true in some of these cases the disintegrating process comes to a standstill and fibrosis sets in—the disease is incapable of cure.' In other words, they all die early; but some don't!" Dr. Lillingston appears here to limit the meaning of the word *fatal* to the sense of *deadly*, ignoring its larger meaning of *inevitable*.

We speak of "*fatal*" results in our manuals of physiology—e.g.: "Reflex Action.—We may define a *reflex act* as the *immediate* motor response to centripetal excitation; it is unchosen, 'fatal'" (Waller). I hope I am not labouring the point in adding the following definition of *fatal*, with examples. Larousse has, "Fatal, e. Fixé irrévocablement par le sort: *les décrets fatals du sort*. Par extension, *Funeste*." "Our *fatal* shadows that walk by us still" (Fletcher).

I am, Sir, yours faithfully,

Worcester, Nov. 11th, 1911. TOM BATES.

EMOLUMENTS IN THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—May I be permitted to comment on that part of the letter of "Civil Surgeon" (in your issue of Sept. 23rd, p. 917) which enumerates five advantages of the Indian Medical Service?

1. "Pay at more than a living wage from the beginning." With this I quite disagree. The pay of some of the billets is a living wage, but there are great inequalities, and nowadays the pay in most billets is only a living wage for bachelors. I myself entered the service near the top of the list; I did not marry till I was 30; I have never played polo or indulged in any expensive sport; I do not drink, or smoke, or gamble. I have had one year of leave home; and I have three children, none of whom have yet been to school. So far from my pay and what I have been able to make by private practice sufficing to meet my expenses, I have spent in addition about £1500 of my own and my wife's money in little more than a decade of service. Had we not had these private means we would be bankrupt. They are now exhausted, and although I have not been home for nearly eight years, I cannot now afford the expense of going home. My wife's life is made miserable by a constant struggle to economise.

2. "An extremely liberal scale of pensions ....." If these pensions were sufficient in years gone by they have depreciated in value now owing to the increased cost of living at home. Moreover, officers in the old days were able to save money to supplement their pensions. Now the great majority of officers can hope to save nothing, or next to nothing. They compare unfavourably with the £1000 a year of the I.C.S. after 25 years' service.

3. "One year's holiday for every three years' work." This is an absolute error. The maximum furlough is one year in every five, if we can be spared. But the service is kept at such a strength that this amount of furlough is not possible to everyone, and I have met few officers who have been able to get all the furlough due to them. Even if it could be got it could not all be taken by officers, on account of their not being able to save sufficient money to afford it. Another thing which prevents furlough being taken is the rule that after taking furlough, or other break in service, as when an officer has gone sick and has had to have sick leave, no more furlough can be taken for three years. This regulation does not figure in the inducements held out to men about to enter the service.

4. "A variety of work and appointments, so that the most diverse temperaments and capabilities can get the sort of 'job' they like. ....." Some do; but the Government has to fill all its billets and a great many men are compelled to serve in uncongenial employment. Within recent years, to gain efficiency and effect economy, the Government has put the entire jail service into the hands of the Indian Medical Service, and it has told men that their only hope of civil employ was in the jail department. Nearly all civil surgeons are burdened with district jails, and the number of purely medical appointments in the Indian Medical Service is really very few.

5. "The privilege that the men with whom you have to work are, as a rule, educated gentlemen of your own social class." I do not quite follow what "Civil Surgeon" means here. If he is talking of civil surgeons, all I can say is that the ordinary civil surgeon is the only bird of his kind in the district, and he hardly ever gets the great privilege of consultation and converse with another medical man of his own kind. It is one of the great drawbacks of the service to anyone who is keen on the scientific and intellectual side of his profession. This isolation is one of the reasons why less original work has been done in Indian medicine than one would have expected from the high standard of quality of the men who have hitherto entered the Indian Medical Service.

I am, Sir, yours faithfully,

Oct. 18th, 1911. ALSO A CIVIL SURGEON.

THE DEMAND FOR PUBLIC ABATTOIRS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 1368.)

THE EXPORT ABATTOIR OF COPENHAGEN AND THE IMPORT ABATTOIR OF MANCHESTER.

The Copenhagen Municipal Abattoirs.

WHEN describing the deplorable condition of the Newcastle slaughter-houses reference was made to Copenhagen. The Danish capital is just on the other side of the North Sea, and there is much intercourse between the two ports. The Copenhagen municipal abattoir is not built after the latest model, nor is it kept so clean and in such good order as to rival the best abattoirs of Germany and Switzerland; nevertheless, it is a very fine institution. The inhabitants of Newcastle should go over on their holiday trips to see what their maritime *vis-à-vis* has done. The Copenhagen municipal abattoir consists of several buildings, with much open space between ornamented with trees or bushes. To my mind, however, the structure in which the horned cattle are slaughtered seemed rather low and dark. It is paved with large cemented flagstones draining into a couple of gutters near the centre of the building. Large windows face each other, and there is an opening along the apex of the roof through which the air passes freely. When the cattle are brought to be slaughtered no attempt whatsoever is made to screen from them the sight of blood and of killing. A good deal of the blood is lost, and though it may not be of much value, still it can be utilised, and unnecessary waste should not be allowed. Above, the rafters are of iron and painted. This is good, for the roof is non-absorbent and easy to clean. The walls are of glazed or enamelled brick up to the height of 10 feet and then of ordinary brick. It is claimed that they are frequently cleaned, but I felt inclined to demur as to the frequency of the process. There is an absence of the smartness and brightness about the place that make German abattoirs look so tidy and clean, and almost disguise the sinister nature of the work for which they are intended. Also there are not sufficient mechanical appliances. Thus men have to lift the carcasses up to hang them on hooks on each side of the slaughter-house. This, of course, should be done with a rope and pulley attached to a travelling overhead rail.

Details of the Work.

If a carcass is found to be affected with tuberculosis all the diseased parts are cut away and the rest is stamped as second-class meat and sold. Every month a notice is published in the papers warning the public that such meat should be very carefully boiled. Of course, these notices do not suffice, for there is no guarantee whatsoever that the advice is followed. For anything we know to the contrary

some of the meat may be sold at restaurants in the form of underdone grilled steaks. Also some of this second-class meat may, when carefully trimmed, look very good and tempting. It would be far safer to boil it and see that it is thoroughly sterilised in the abattoir before allowing it to be sold for human food. A boiling place for feet and calves' heads already exists, and it is much better to do all necessary cooking on the premises before selling the meat to the public.

There is naturally a separate building for the slaughtering of swine. Here some men are employed during all their time to keep the place clean; they are not, however, very successful. Every year one of the buildings or slaughter halls is repainted. Evidently they were not all built at the same time and those that are more recent are better devised. There is one large double-sized hall with a low partition down the centre which is preferable to the others. It has more window space and light from above. A smaller building is reserved for a horse slaughter-house, and in this, as is so frequently the case where horses come with their iron hoofs, the pavement was in need of repair. Then there is the large export slaughter hall where cattle are killed for foreign consumption. It is a fine building and should interest British visitors, as a good deal of the meat derived from the animals killed here is exported to and consumed in Great Britain. (In the Manchester meat market I came across a good deal of Danish beef; it is very popular in Lancashire, because it is lean and there is very little waste.) The greater part of the roof is lantern-shaped, with windows opening all the way round. Below the walls have large windows and the doors are wide. It should be easy to keep the place clean and sweet if the viscera were promptly removed, the intestines cleaned, and the pouches emptied in premises specially constructed for this very unpleasant work.

The Good Points at Copenhagen.

What is really good about the Copenhagen municipal abattoir is the ample space, the broad avenues planted with trees, and the absence of high buildings and of inhabited dwellings close by. The pens also are good, especially those allotted to the big cattle. The flooring is carefully laid to provide a sufficient slope so that all liquids easily drain away to the gutters that are on each side of the central passage. A long trough goes all the way round in front of the cattle, and there is a continual current of fresh water passing before them. The roof is not so lofty, but it lets air and light pass freely. There is naturally a small slaughter-house especially reserved for killing animals known or believed to be unhealthy, and there is also a small building for keeping condemned meat till it can be conveyed to the destructor, which is some distance away. The veterinary surgeons are easily recognised by the uniform cap they wear, and are always present when the slaughtering begins. They are employed and paid by the municipality and not by the butchers, so they have no interest to serve by concealing or acting leniently where anything suspicious is found. Complaints are made that the abattoir costs a great deal of money. Nevertheless, it may be said that in round numbers for every £30 spent £35 (or £5 net profit) are received. This seems a very good return, though with better organisation and greater care bestowed on the utilisation of the by-products a much larger profit might be cleared.

The Manchester Foreign Animals' Wharf.

Sufficient reason has been adduced to show that a municipal abattoir should be built at Newcastle without further unnecessary delay. There are cogent reasons why this is also necessary at Liverpool. The difficulty in England is the tendency to tinker and to compromise. For instance, taking the great roads for international traffic from East to West, Scandinavia, Copenhagen, and Holland send over meat to England viâ Newcastle and Hull, and emigrants land at the same time to be transmitted to the ships that sail for America from Glasgow and Liverpool. What has been done to deal with this trade in a scientific and sanitary manner? One of the best enterprises has been the foreign animals' wharf on the Ship Canal, constructed by the Manchester corporation at Old Trafford. It was opened in 1895, and ships of 5000 to 6000 tons can come alongside and land cattle immediately opposite their pens. Alley ways with strong wooden swing gates are so contrived that the cattle on landing from the ships cannot go astray and cannot turn back, but must go forward till they reach the stables that have been assigned to them. These are lofty and airy, though the floors are slippery and do not seem well drained. When, however, the sewage does ultimately reach a gutter and a drain it flows into two brick tanks that are 26 feet below the floor level of the wharf. These tanks are just behind the engine-house. There is a suction pipe, so that the contents are raised daily and pumped into the neighbouring main sewer. Thus a sufficient fall can be obtained in all parts of the premises to drain away surface water even if mixed extensively with blood and sewage. But the manure and heavier refuse matter is not drained into the sewers. There are three jetties, and the big ships land the cattle at the end of these piers. By the side of the piers barges are moored, and these will hold from 50 to 80 tons of manure; thus there are no manure heaps and no manure is kept on the premises. This is an illustration of the use of a waterway by the side of an abattoir.

Insufficient Slaughtering Accommodation.

There is room at the Manchester Foreign Cattle Wharf to place in comfortable stables 2000 cattle. The more recently built lairage is less lofty, easier to keep warm, but there are louvred openings the whole length of the roof and there is plenty of light. The buildings are very broad, and there is room inside for many rows of cattle, separated by cast-iron posts and wood cross rails, with gates that open into the stalls and close the passages, or open the passages and close the stalls. Overhead there is nothing but the roof, which is lantern-shaped all the way down the centre, with a louvre opening on each side. Then half-way down the broad roof that slopes from the centre to the outer walls the slate tiles are replaced for some feet by window panes which let through a stream of light. These lairs are certainly more satisfactory than the slaughter-houses. The latter are lofty, with walls of white enamelled bricks; there is an opening at the apex of the roof and louvred windows at each end are kept bright and clear. Immediately outside there are small pens where the cattle wait their turn to be pole-axed, and there is a contrivance by which a rope passed through the wall enables the butcher to pull in the animal without risk of being hurt. The doors on the opposite side, and these are sliding doors, face the cooling room, which is reached through a covered way, where are overhead rails to convey the carcasses. Here 500 "sides" may be hung. Then at one end of the cooling room there are three cold storage or chill rooms, each holding 174 "sides." All this is conveniently arranged, but the slaughter-houses themselves seemed to me too small. Instead of a large hall there are five slaughter-houses with two killing floors in each, and these measure only 33 by 45 feet. It would not be possible to kill more than 20 cattle simultaneously, and as there are sometimes as many as 300 cattle waiting to be slaughtered this means working under pressure for as long as seventeen hours. This is wrong from every point of view. It is injurious to the health of the workers and likely to lead to carelessness.

Overlapping and Confusion of Authority.

Nearly all the slaughtering consists of horned cattle imported from America. There are a few Canadian sheep and a small pen and slaughter-house for them, and there is also a small slaughter-house on the landing-stage for the killing of exhausted cattle. To decide whether the cattle may be allowed to rest and recoup from the effects of their sea journey or should be killed at once, and to see if they are generally in a healthy condition, both the Board of Agriculture and the Port Sanitary Authority have their staff of inspectors, who watch the living animals and examine the carcasses. But it was a third authority, the Manchester corporation, that built the entire place. Then, again, though the Manchester corporation does not undertake the slaughtering of the animals, it does all the cleaning. It levies a toll of 4*s.* a head on all the cattle. The cost of the food the animals consume is paid by the importers, and the latter attend to the cattle. More extravagant and wasteful than this strange overlapping of authorities and work is the surrender of some of the most profitable side trades. Why have the best paying sections of the work been allowed to slip through the fingers of the Manchester corporation? If the municipality was justified in building

the wharf, which might have been done by private enterprise, it was still more justified in keeping in its own hands a business that may give rise to many unwholesome conditions requiring supervision, but also bring in much profit.

(To be continued.)

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Hospital Sunday Fund.

THE committee of the Hospital Sunday Fund, in presenting its forty-first annual report, regrets that the decline which set in four years ago shows no signs of abating. The receipts from the collections made on Hospital Sunday of 1911 were £6119 against £6162 in the previous year. It is true the decrease was only £43, but the expenses, which in 1909 and 1910 were generously borne by two members of the committee, have this year to be met from the general fund. The total sum available for distribution, after deducting expenses, is £5977, and of this sum £5946 have been paid to the joint fund (Hospital Sunday and Saturday), whilst a balance of £30 12*s.* 3*d.* has been carried forward. The total sum distributed by the joint funds this year was £13,800, as against £14,530 in 1910, a decrease of £730. The charities participating in the distribution are the same as last year, with the addition of the Children's Convalescent Home at West Kirby, to which a grant of £50 was made. One pleasing feature of the report is the generous contribution of £100 made by the Welsh Church committee. The number of churches contributing has risen from 403 in 1910 to 421 in 1911. The committee is unable to claim any grant this year from the kind donors who promised a donation of 10 per cent. on any increase in the total collections of the joint funds.

Liverpool School of Tropical Medicine.

Professor R. Newstead has returned to Liverpool from his expedition to Central Africa. At the special request of the Government the School of Tropical Medicine sent him to Nyasaland in connexion with the sleeping sickness commission which the Government is sending out under Sir David Bruce. Professor Newstead, who has been absent about six months, was recently appointed to the Dalton memorial chair in Entomology at the University of Liverpool.

Mitchell Banks Memorial Lecture.

The council of the University of Liverpool has appointed Professor F. M. Caird, the occupant of the chair of Clinical Surgery in the University of Edinburgh, to deliver this lecture in the session of 1912–13. The lecture, which formerly was delivered annually, has now been altered to a biennial one. It will be remembered that the lectureship was founded as a memorial to Sir William Mitchell Banks, the distinguished Liverpool surgeon, and for so many years professor of anatomy in University College, Liverpool, prior to its absorption in the University of Liverpool. The nomination of Professor Caird is a happy one, and has given much satisfaction to the medical profession of the district.

Liverpool University Association.

The University Association is to entertain as its guest, at the dinner to be held on Dec. 15th, Professor Michael Sadler, the new Vice-Chancellor of the University of Leeds. The Universities of Liverpool and Leeds have been closely associated for many years, and it will be gratifying to members of the former body to show to the new head of the University of Leeds that they desire the close and cordial relations to continue. The dinner will be held as usual at the Adelphi Hotel.

Munificent Gift to Chester Infirmary.

The Duke of Westminster has contributed £3000 towards the funds of the Chester Infirmary for the extension and renovation of the institution.

Typhoid Fever at Skelmersdale.

For the past few weeks the village of Skelmersdale has been suffering from a severe epidemic of typhoid fever. Upwards of 50 cases have been notified, with 5 deaths.

Nov. 14th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Causes of Crippling.

THE report of the physically defective inquiry subcommittee of the education committee previously referred to contains some useful information as to the causes of crippling. An exact diagnosis was made in 721 of the 728 cases under 16 years of age. The percentage of the distribution of the causal disease was as follows: Tuberculosis, 285 (39·5); infantile paralysis, 175 (24·3); rickets, 73 (10·1); congenital deformity, 71 (9·8); apoplexy, 33 (4·6); birth palsy, 25 (3·5); scoliosis, 13 (1·8); pseudo-hypertrophic muscular paralysis, 5 (0·7); progressive muscular atrophy, 2 (0·2); rheumatism, 3 (0·4); necrosis of bone, 5 (0·4); rheumatoid arthritis, 0 3; flat foot, 1 (0·1); achondroplasia, 1 (0·1); and accident, 25 (3·5). The accidents were mainly burns or being run over. 24 cases due to apoplexy or birth palsy were found to be also mentally defective and have been excluded from the list. Of 828 cases over 16 years of age the diseases were: tuberculosis, 206 (24·9); accidents, 133 (16·1); apoplexy and birth palsy, 116 (14·0); infantile paralysis, 73 (8 8); rheumatoid arthritis, 29 (3·5); rheumatism, 33 (3·9); rheumatic fever, 10 (1·2); congenital deformities, 47 (5·7); venereal disease, 39 (4·7); spinal myelitis, 11 (1·3); cerebral tumour, 3; paralysis agitans, 3; spastic paraplegia, 5; anterior poliomyelitis, 3; disseminated sclerosis, 2; 1 case each was due to amyotrophic lateral sclerosis, Friedreich's ataxia, lumbar pachymeningitis, cerebro-spinal meningitis, progressive muscular atrophy, congenital muscular atrophy, alcoholic neuritis, amputation for gangrene following typhoid fever, diabetic gangrene, flat-foot, frost-bite, white-leg, elephantiasis following scarlet fever; 8 were due to amputation for blood-poisoning and scoliosis respectively, 7 to rickets, 5 to amputation for tumour, 4 to septic poisoning, 3 to muscular dystrophy and necrosis of bone, 2 to lead-poisoning and fragilitas ossium; 60 were unclassified. Two of the cases of septic poisoning followed childbirth. The number of cripples due to tuberculous disease rapidly diminishes as age advances; thus there are 285 cripples under 16 years of age, 117 between 16 and 30, 55 between 30 and 45, 22 between 45 and 60, and 12 over 60. The records for infantile paralysis are somewhat similar, 175 under 16, 39 between 16 and 30, 22 between 30 and 45, 12 between 45 and 60, and none over 60. One of the chief objects of the inquiry was to obtain information about accidents. Of the 133 cases of permanent crippling over 16 years of age due to accidents, 92 were males and 41 females; there were 2 between 16 and 30, 31 between 30 and 45, 50 between 45 and 60, and 30 over 60 (the ages refer to the age of the cripples at the time of examination, not at the time of the accident). Of the 133 accidents, 51 occurred at work, 59 not at work, and in 23 the mode of occurrence was not ascertained.

Birmingham Medical Mission.

The annual report shows that during the past year the buildings have been considerably extended. The total number of cases was 7558, making 33,408 attendances, including 1950 visits at home by the medical superintendent. The work is done in harmony with the efforts of the medical officer of health and the medical officers of the education committee. Children are protected from overwork at school or encouraged to attend regularly as the case requires. Others are introduced to the open-air school, and very many are recommended to convalescent homes and special hospitals. The committee makes an appeal for £250 to enable it to meet the extra expenditure of the year.

Nov. 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University and Degrees in Veterinary Medicine.

THE question of an Edinburgh University degree for veterinary students has been referred to from time to time. Not only have negotiations been satisfactorily concluded, but a draft ordinance has been approved by the University Court, the scheme of which I have already alluded to in your columns. By the full scheme it

is proposed to have two degrees—viz., Bachelor of Science and Doctor of Science—in this department. For the B.Sc. the following conditions are required: 1. Four years of study in veterinary medicine. 2. The candidate must be a Member of the Royal College of Veterinary Surgeons or hold a veterinary diploma entitling him to be registered. 3. In addition to the courses prescribed for the diploma of the Royal College of Veterinary Surgeons, a course of instruction must be taken in the following subjects: practical chemistry, physics, advanced or applied botany or zoology, anatomy of domesticated animals (including embryology and practical anatomy), histology, experimental physiology and physiological chemistry, pathology and bacteriology, protozoology and entomology, sanitary science and veterinary hygiene, and genetics (heredity and the principles of breeding). Attendance at the Royal (Dick) Veterinary College, Edinburgh, shall qualify *pro tanto* for admission to the University examinations. One year of study must be spent at the Edinburgh University, and the Senate is given the power from time to time to determine the proportion of classes to be taken at the University and at the Royal (Dick) Veterinary College. The University Court is given power to determine what other courses of instruction may be accepted by the University other than those mentioned. The examination for the degree of B Sc. is to consist of three divisions:—First division, chemistry, physics, botany, and zoology; second division, anatomy (including embryology and histology) and physiology; third division, pathology (including bacteriology, protozoology, and entomology), genetics, and sanitary science and veterinary hygiene. Graduates who have held the degree of B.Sc. for three years may offer themselves for the degree of Doctor of Science. Such candidate shall be required to present a thesis or a published work or memoir on a subject bearing on veterinary science or practice. It is provided that this ordinance shall come into force at the beginning of the winter or summer session next after the date of its approval by His Majesty in Council.

Aberdeen County School Medical Inspection Staff.

At a meeting of the Aberdeen County Committee on Secondary Education, held on Nov. 10th, a report was read as to the carrying out of the school medical inspection for the current year. The number of children inspected last year was 9655, and the estimated number to be examined this year is, counting those who have to be re-examined, 15,691. The report pointed out that a third medical officer was urgently needed, and raised the question of the coöperation of nurses in the work of medical inspection in the county. A motion was carried that the matter be remitted to the Medical Inspection Subcommittee for consideration and report.

Nov. 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Insurance Bill in Ireland.[1]

THE amendments put down by Mr. Lloyd George for the Irish portion of the Insurance Bill show that, so far as Ireland is concerned, it is really a new measure, and that an attempt has been made to meet the two diverging views of the Irish Nationalist party. "Medical benefits" are left out, but the Irish dispensary doctors are to give the certificates needed for sickness, &c. This plan will satisfy the representatives of the rural districts, while the clause by which "medical benefits" may be introduced as an additional benefit by the members of an approved society should be approved by the Members who represent industrial centres. As a result many fear that, instead of getting away from the Poor-law system, its methods will be intensified, while the very club practice which the members of the medical profession in England want to get rid of, and which up to the present has taken little root in Ireland, will now be fully installed here. The real mistake made by the medical profession was in not insisting that under no circumstances would they agree to the contract system of medical attendance. This would have been logical.

[1] See Parliamentary Intelligence for notes on the progress of the National Insurance Bill.

Boarding-out of Workhouse Children.

Lord Mayo, who last week led a deputation to the Local Government Board from the Irish Workhouse Association, pointed out that although 2593 children were being boarded-out, 7279 were still housed in the workhouses. Moreover, 32 unions had taken no steps to board-out any children. The Vice-President of the Local Government Board expressed sympathy with the objects of the association.

The Milk-supply in Ireland.

The *Dublin Gazette* of Nov. 10th announces the appointment of a Vice-Regal Committee "to inquire into the alleged scarcity in the supply of milk in some parts of Ireland, and to report upon the causes of the deficiency, where it exists, its effects upon the public health, and the means whereby the deficiency can be remedied; and also to inquire into and report upon the dangers of contamination and infection in the present milk-supply, and the methods best adapted to guard against these dangers." The chairman is Mr. P. J. O'Neill, J.P., chairman of the Dublin county council, and the other members are Sir John Lentaigne, F.R.C.S. Irel.; Mr. George A. Moorhead, F.R.C.S. Irel.; Mr. Alec Wilson, of Belvoir Park, Belfast; Mr. Dermod O'Brien, president of the Royal Hibernian Academy; Mr. John R. Campbell, B.Sc., assistant secretary in respect of agriculture of the Department of Agriculture and Technical Instruction for Ireland; Mr. Albert E. Mettam, B.Sc., M.R.C.V.S., principal in the Royal Veterinary College of Ireland; Lady Everard, of Randlestown, Navan; and Miss Margaret McNeill, assistant inspector of reformatory and industrial schools, Ireland. It seems unfortunate that the committee should not contain any medical officer of health experienced in dealing with milk-supply. The appointment of the committee has caused surprise, as it is generally thought that if the Local Government Board enforced the Dairies and Cowsheds Order the conditions of the milk-supply in Ireland would be satisfactory. The absence from the committee of a representative of that Board has also caused surprise.

Accommodation for Consumptives in the Royal Hospital for Incurables.

A "public" meeting was held last Monday to protest against the proposed building of a new pavilion for consumptive patients at the Royal Hospital for Incurables, and several speeches in opposition thereto were delivered. Mr. Mahony, consulting surgeon to the hospital, as well as a member of the managing committee, were refused a hearing by the chairman. Mr. Mahony's undelivered speech, subsequently published, showed that the increased accommodation is only from 69 beds to 80. It is to be hoped that the governors will not be deterred by the opposition in the neighbourhood from making the very necessary addition they propose.

"Ui Breasail."

The total receipts of Ui Breasail, the Health Exhibition held at Bates Bridge, Dublin, in May and June last, amounted to £9956 6*s.* 11*d.*, and the expenditure to £7437 14*s.* 7*d.*, leaving a net profit of £2518 12*s.* 4*d.*, more than £1500 of which came from donations. The financial result is disappointing, but the exhibition must be credited with some educative effects. The accounts do not give sufficiently detailed information to justify an opinion as to where the wastage occurred.

A Degree of Sc.B. for Dublin University.

Hitherto Dublin University has conferred only a doctorate in science. In future a degree of Sc.B. may be conferred, for research and advanced study in any important branch of mathematical, experimental, natural, or applied science, on Dublin graduates who have obtained moderatorship in mathematics, experimental science, or natural science, provided one full year after graduation shall have been devoted to any important branch of any of the above-named subjects, both by study and research. Graduates of other universities holding a degree equivalent to the moderatorship shall be eligible on like conditions, provided the year's study and research is passed in residence at Dublin University. Graduates of Dublin or other approved university who have not obtained moderatorship or its equivalent may qualify for entry on the year's course as above by presenting themselves at the moderatorship examination for the intended study and obtaining therein qualifying marks for moderatorship.

The Belfast Water-Supply.

At a recent meeting of the Belfast water commissioners, in discussing the question of an emergency supply from Lough Neagh, it was stated that Lough Neagh had been considered as a source of supply, but experts had advised that it would be dangerous as it received the sewage of various towns. The medical officer of health of Lurgan, Dr. Samuel Agnew, in rejoinder, showed at a meeting of the Lurgan town council that the same statements, supported by the same authorities, had been subsequently made when Lurgan was deciding on its water-supply. They, however, decided to get their supply from Lough Neagh, one inch of water from the surface of which supplied 2,000,000 gallons. The lough covered 100,000 acres, and had a maximum depth of over 100 feet, and a minimum depth of over 25 feet. Such an enormous storage reservoir acted as a great purifying agent, and when the water was pumped up to Lurgan, and there filtered, it became a water of exceptional purity and reliability. The results of analysis made by the Clinical Research Association of the water taken from a tap in the town of Lurgan showed that it was of a high degree of bacterial purity. The freedom of Lurgan from disease communicated by infected water was an additional practical proof of the purity of the Lough Neagh supply.

Belfast Asylum.

In the report of the inspector, Dr. W. R. Dawson, just issued, it is urged that the erection of villas at Purdysburn Asylum should be pushed on, so as to complete as soon as possible the transfer of all the patients there, and so avoid the expense of maintaining two institutions, with the overlapping of staff rendered necessary in some departments.

Alleged Pollution of a River.

At the recent Castlebar sessions, before Judge Doyle, the Marquis of Sligo brought suit against the Westport urban council, seeking an order from the court under the Rivers Pollution Act to restrain the council from allowing the sewage of the town of Westport to flow into the river, which runs through the town and Lord Sligo's demesne to the sea. Evidence was given that the sewage of the town was discharged into the river, and that the latter was in consequence very offensive. On the other hand, it was alleged that there was no nuisance. His honour reserved judgment till the January sessions.

Typhoid Fever in Omagh Asylum.

Referring to the outbreak of typhoid fever in Omagh Asylum chronicled last week the report of the resident medical superintendent, presented on Nov. 9th, showed that the water and the farm milk had been inspected and reported as all right, and the sewerage had also been examined without revealing the cause of this sudden outbreak. It was decided to employ an expert to make a test of the sewers, water-supply, and drainage of the institution, and to report thereon and make recommendations to the committee. At a meeting of the Omagh rural council held on Nov. 11th, in reply to the Local Government Board, asking why no action had been taken in regard to the report of Mr. J. J. Todd, medical officer of health of Omagh [1] as to the nuisance caused by defective sewerage at the lunatic asylum, the chairman said that the asylum authorities had not yet ascertained that the sewerage was at fault. This was the third outbreak at the asylum, and they had been unable to trace the source. Probably the disease broke out through some individual coming to the asylum (? a typhoid carrier). To a question asked by one of the members of the rural council, "Would the sewage passing through Omagh not carry infection?" no answer was given. The Local Government Board is bound to see that sewage from a typhoid-infected institution shall not be discharged untreated into the river passing through the town. This is the point raised by the medical officer of health. On Nov. 13th the deaths numbered eight.

A Parsimonious Board of Guardians.

At Enniskillen quarter sessions, on Nov. 1st, Mr. John Wilson, of Enniskillen, sued the Enniskillen board of guardians for 3 guineas fees and 15*s.* car hire. On August 24th, on a telegram from the relieving officer, Mr. Wilson drove by car to Jubapeeney, county Cavan, 17 miles distant, to attend an operative midwifery case. On reaching the pass leading to the house he had to walk three miles through heather, and over rocks and through a bog. The guardians tendered Mr. Wilson 3 guineas, but objected to pay the car hire. Judge Craig, K.C., said that, if necessary, the doctor should have taken a motor-car. Where the lives of a mother and child were in danger no expense should be spared. It was the duty of the medical officer to take the quickest route. He gave a grant for the full amount claimed.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Reunion of Provincial Sanitary Officers.

THE heads of the Bureaus of Hygiene of towns of more than 20,000 inhabitants and the departmental inspectors of hygiene met recently at the Pasteur Institute, under the presidency of M. Vaillard, Medical Inspector-General of the Army. Among those present were by M. Jules Renault, Inspector-General of the Sanitary Service; M. Mosny, Secretary-General of the Congress; M. Vincent, Professor at the Val de Grâce; and M. Chassevant. M. Diénert, Chief of the Water Inspection Department of Paris, made a report on the selection, securing, protection, and surveillance of water destined for drinking purposes. Dr. Mauriac, Inspector of Hygiene of the Gironde, presented a communication on the measures taken at Bordeaux against the invasion of cholera by land. Dr. Marchoux reported on the epidemic of typhoid fever which has prevailed in Paris and in the department of the Seine during the past three months. He said that the Paris water-supply must not be held solely responsible for the recrudescence of the disease, but that the outbreak was rather due to the return to Paris of persons who had contracted elsewhere the germ of the disease. The drinking water of Paris, according to him, is superior to that of many other places, and it should not be spoken ill of. Dr. Marchoux then detailed the various procedures employed to discover the source of the fever, and, finally, he stated that the different vaccines that had been tried had given no good results, with the exception of one constituted of sensitised bacilli—that is to say, cultivated in typhoid serum.

Blennorrhagic Arthritis.

M. Ramond on Nov. 3rd recommended, at the Société Médicale des Hôpitaux, a procedure used by himself in blennorrhagic arthritis when all other therapeutic measures had failed, before having recourse to surgical intervention. He withdraws by puncture from 3 to 5 c.c. of synovial fluid and immediately re-injects it under the skin of the articulation; then a compress of cotton-wool is applied. The injection may be repeated every two or three days if necessary. A cure without ankylosis is usually established in eight or ten days. M. Ramond has treated several cases of arthritis of the knee in this manner, two of which were apparently very serious, for the fluid in them was decidedly purulent. Nevertheless, as microscopic examination did not demonstrate the presence of the gonococcus among the pus cells, M. Ramond did not hesitate to inject the joint contents, but used only 1 cubic centimetre for the first injection. The injection was well borne, as also were the following ones, which were made in stronger doses of from 2 to 5 cubic centimetres. The same procedure gives results equally encouraging in hydrarthroses of all kinds.

The Consequences of the Excessive Heat.

Dearness of provisions and dearth of milk and other foodstuffs have not been the only results of the excessive heat of the past summer; it has unfortunately had a more direct influence on the public health, and the gastro-intestinal and hepatic troubles induced by it have formed the subject of a special study by M. de Fleury. These troubles have been attributed generally to the increased use of iced drinks. This cause may, it is true, hold an important place, but besides this the heat has had a great influence on foodstuffs of animal origin by hastening putrefaction, thus augmenting the virulence of the intestinal pathogenic microbes. It provokes an almost complete substitution of perspiration for micturition, but sweating

cannot make up for the renal insufficiency. The inadequate elimination thus produces an intoxication. Finally, the excessive heat appears to over-work the glandular apparatus and thus to diminish the protective powers of the organism. M. Fleury proposes, in order to augment the renal secretion at the expense of the cutaneous, a *régime* devoid of all food of animal origin, such as milk, eggs, fish, and meat, intestinal antisepsis by means of lactic ferments, and the raising of the blood-pressure in the renal artery by means of theobromine, together with small doses of caffeine.

Death of M. Henri Monod.

M. Henri Monod, a member of the Academy of Medicine, died recently at the age of 68 years. For upwards of 20 years his administrative career had been devoted to questions of public assistance and hygiene. In 1887 he was named Director of Public Assistance at the Ministry of the Interior, to which was added two or three years later the section of public hygiene. As a commissary of the Government he was very active in promoting the law for the protection of the public health, which was, in fact, almost entirely his work.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A Proposed Reform of the Law Relative to Occupational Diseases.

IN an article on the diseases and accidents to which workmen are liable Dr. Roth has stated in the *Aerztliche Sachverständigen-Zeitung* that the number of accidents due to the fault of employers has decreased from 20 per cent. in the year 1887 to 12 per cent. in 1907, but that the accidents due to the workmen themselves have, on the contrary, increased during the same period from 27 per cent. to 41 per cent. He is of opinion that the increase was not caused so much by the carelessness of the workmen as by fatigue. He believes that the considerable diminution of the hours of work enforced by the law necessarily induces quicker working, and that this fact may possibly be the cause of the increase of accidents due to the fault of the workmen. One of his recommendations is the employment of factory inspectors for the various trades. As regards the diseases commonly associated with certain trades, it is stated that notwithstanding the sanitary regulations a decrease of those diseases has either not taken place at all or not in proportion to the improvement of the sanitary condition of factories and workshops. The number of cases of lead poisoning has increased from its former proportion of 12·2 per cent. to 19·1 per cent. in 1908. Dr. Roth earnestly advocates medical inspection of all the factories where the work is dangerous to health, and recommends careful investigation into the cause of the individual cases, as is prescribed by the existing law regarding accidents. The medical inspection ought to be particularly strict with respect to youths and working women, the latter showing a mortality far above the average—a fact which is the more remarkable as women are by law excluded from a great number of unhealthy or dangerous occupations. The notification of every case of a trade disease ought to be made compulsory, he considers. The number of cases of trade diseases is not extremely great here. In the Berlin municipal hospitals—which, of course, are only a section of the Berlin hospitals—the number of cases of lead poisoning is only 91 per annum, of which 50 per cent. recovered, the remainder being discharged as either relieved or unimproved. Other examples of trade diseases are eczema caused by chemical substances and poisoning by carbonic oxide. When these cases are notified and treated at an early date the patients occasionally recover completely in a short time. Tuberculosis is, of course, in many cases due, at least indirectly, to employment in dusty workshops, but notification of this disease is not yet possible because the connexion between the disease and the trade cannot be exactly ascertained in every case. The new reformed law for the insurance of workmen is a great improvement, because it empowers the Federal council to stipulate that certain trade diseases may come under the provisions of the statutes relative to insurance against accidents, so that workmen unable to follow their employment through suffering from the diseases in question are entitled to compensation, as in the case of an accident.

Modern Treatment of Inoperable Cancer.

At a recent meeting of the Association of German Naturalists and Medical Men Professor Czerny, of Heidelberg, read a paper on the Modern Treatment of Cancer. He said that the principal points in rational treatment were an early diagnosis and an early operation. The results of treatment in advanced cases not permitting an operation would continue to be unsatisfactory as long as the causes of the disease remained unknown, and surgeons must therefore in these cases be content to relieve the sufferings of the unfortunate patients. As a result of recent researches it has been stated that certain lipoid substances produced a strong cancerous proliferation of the epithelial cells. These substances were possibly active in the development of the forms of cancer affecting chimney-sweepers, aniline workers, and tobacco-smokers. The Roentgen rays, by producing dermatitis, prepared a precancerous stage, leading sometimes to real cancer. Chronic irritation of ulcers and scars of the skin, or of the gastro-intestinal mucosa, or of the gall-bladder, might bring on cancer by the action of an unknown irritant and where predisposition existed. Nearly all statisticians declared that cancer was increasing in every civilised country. The increase was not uniform or steady, but occurred epidemically, in certain places more than in others, and in certain times it ceased altogether. Special researches carried out by Dr. Werner in the grand-duchy of Baden had shown that the exciting cause of the disease was present either in the soil or in the houses in which the patients had been living, that the time of incubation was rather long and that the germ was not conveyed from man to man. With regard to modern methods of treatment, Professor Czerny said that to avoid the possibility of cancerous tissue being left in the wound and producing a local relapse he was accustomed to operate in two stages; after the operation the wound was left open and then electrical fulguration, diathermy or exposure to radium rays or Roentgen rays, was resorted to. After three months had passed without the occurrence of a relapse the wound was closed by a plastic operation, and in order to avoid dispersal of the cancerous germs the tissues were cut by an electric cautery instead of a scalpel. Professor Czerny made frequent use of radiotherapy, more than two-thirds of his cases being inoperable. Radium rays and Roentgen rays destroyed the cells of the growth, the tumour becoming smaller by necrosis. Owing to their anodyne effect the patients liked to have the rays administered, although a radical cure was not produced, the cells, but not the germs, being destroyed by the rays. Injections containing preparations or emanation of radium had proved unsuccessful, the insoluble preparations being encapsuled, and thus rendered inert, while the soluble ones passed through the body too quickly to become effective. Salvarsan administered by subcutaneous and intravenous injection has given some suggestive results in sarcoma, but in cancer it was only used in the form of injections within the growth to produce necrosis. The effect of serum-therapy and treatment with antitoxin was not yet sufficiently tested. Professor Czerny then showed three cases of inoperable cancer of the stomach in which he had made the growth accessible and had then given an exposure to the Roentgen rays, with the result that the pain was much relieved. In another case of cancer of the cardia gastrotomy was performed, and the Roentgen rays were applied through the fistula. The growth was then drawn through the fistula and cauterised by an electric cautery. The fistula was sutured a fortnight afterwards on the special desire of the patient. Professor Czerny said that in the cancer hospital at Heidelberg it was found that real cancerous tissue might be successfully destroyed by physical means, but he was opposed to this method of treating patients who were in a cachectic state and had internal metastases.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Medical Prospects in South Africa.

NEARLY every local practitioner of any standing has his advice sought from time to time by younger colleagues of his acquaintance in the old country as to the prospects of medical practice in South Africa. There are very few who would advise any home-born practitioner to emigrate to South

Africa at the present time, for the opportunities afforded newly arrived practitioners are by no means attractive. There can be little doubt but that the Union is overstocked with medical men, and the ranks of the local profession yearly are becoming more and more overcrowded and out of all proportion to the increase in the European population. In the larger towns competition has been very keen for years past, and the same is becoming more and more evident in the villages and hamlets. In most country villages one now finds two or even three practitioners where there is really only a proper living to be made by one. Moreover, the expenses of living do not tend to cheapen, and South Africa must still be regarded as one of the most expensive places in the world in which to live—at any rate, with the same standard of comfort as in Britain. The home-born practitioner desiring to emigrate has, perhaps, a better chance of success in the towns than in the country, for though competition is very keen in the former, a newcomer who is prepared to wait can, as a rule, eventually establish himself in practice. In the villages, unless he is very lucky and able to find a place where the opposition is exceptionally weak, he does not stand much chance of success. In most country villages he must equip himself with a good working knowledge of the Taal, but even with this he will usually find that an Afrikander opponent will have the advantage of him, not only in selection for all public appointments, but in private practice as well. It is true that the day has gone when the British practitioner is boycotted on account of his nationality, but, nevertheless, if in a Dutch district he is opposed by an Afrikander practitioner he will find out, unless his opponent be extraordinarily incompetent, that the practice will become divided up to a very large extent on racial lines, and in case of a public medical appointment falling vacant in his district both Church and State will be arrayed against him should he seek preferment.

Apart from present difficulties, it is rumoured that a new Medical and Pharmacy Act has been drafted for the Union on radically different lines to that drafted for the assistance of Government by the medical councils of South Africa. It is stated that the draft Act contemplates the opening up of the country to all practitioners who are qualified to practise in their country of origin. It is to be hoped that the rumour is not true, for it would virtually mean that South Africa will be again over-run with the quack and the charlatan; even if this could be guarded against, inevitably there would be a lowering of the ethical code, which, under present circumstances, is by no means on as high a level as could be desired. One feels that the rumour is likely to be true, for it is notorious that several of the present Ministers have expressed themselves at various times in favour of opening the gates of practice to the talent of all nations. It is well known, also, that one Minister at least has stated his rooted objection to the Medical Council system, and it would seem likely, therefore, that the new legislative proposals may not enable disciplinary action to be taken in case of professional misconduct. For years past Ministerialist organs have expressed disapproval of the powers conferred upon the medical councils of the Provinces. Only the other day *De Volkstem*, which is supposed, as a rule, to reflect Ministerial opinion, had fault to find with any law which protected medical practitioners by penalising those who practise without a licence. It quoted the case of the cancer quack, Mrs. Van Niekerk, who, it contended, proved conclusively that she had greatly assuaged the sufferings of those whom doctors from "Oxford and Cambridge" had given up as hopeless. It omitted to mention, however, that the claims of Mrs. Van Niekerk to cure cancer were carefully sifted by a Select Committee of the House of Assembly at the Cape some years ago and were found wanting, and that this person has been repeatedly fined by magistrates and was once indicted for manslaughter for causing grievous bodily harm to a patient which resulted in death. *De Volkstem*, in the same article, recalls how in their wanderings on the Great Trek, the Boers of old were entirely dependent upon the skill of wise women and of others who had gained a knowledge of medicinal herbs and of simple remedies, and that they managed very well for years without licensed doctors. The article concludes by insinuating that the reason for the high death-rate in the concentration camps was because medical men and not "wise women" were employed. Apparently the author of this effusion would have the profession legislated out of existence; though *De Volkstem's* opinions on the need or otherwise for stringent laws to govern the medical profession and to safeguard the public are doubtless not a proper reflection of ministerial views, the article is significant in that it does represent undoubtedly the views of the "backveld" Boer. Under all the circumstances one would be inclined to issue a strong warning to any practitioner thinking of settling in South Africa to the effect that for the present, at any rate, this country has little to offer to any newcomer who has to earn his living by means of his profession.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Malaria in the Punjab.

A NOTABLE Government report[1] has been issued, entitled "Malaria in the Punjab," which deals specially with the great epidemic of 1908, when Amritsar suffered so severely and the province lost 307,300 persons in a little over two months. The Punjab, it may be stated, is the only province in India which suffers with any frequency from terrible autumnal epidemics of malaria. Major S. R. Christophers, I.M.S., writer of the report, distinguishes between ordinary seasonal malaria of the autumn and the fearful epidemics of malaria which occur in certain years and which wipe out the inhabitants of cities and villages. This virulent type he calls "fulminant malaria" As an example of the ravages of this "fulminant" type of malaria may be cited that of the city of Umballa, which lost in the month of October, 1890, no less than 17,025, a death-rate of 1200 per cent. above normal! Major Christophers says he at first thought the epidemic of 1908 to be quite unique in its virulence, but when he examined the facts of the last fifty years he was surprised how frequently such serious outbreaks had occurred. The worst years have been in 1876, 1878, and 1879, then the years 1890, 1892, and 1894, and in the present century 1900, 1901, 1903, and 1908. He found that the difference in the years was so marked that while in 1905 and 1907 the autumnal mortality was between 60,000 and 80,000, in 1900 and 1908 it was between 250,000 and 300,000. He therefore made a careful study of the causes of these variations. One obvious factor, of course, is the rainfall. Heavy autumn rains in the Punjab mean a spread of malaria. The following figures show the importance of this factor: For 20 years in which rainfall was deficient the average mortality was 81,000; for 10 years in which rainfall was normal the average mortality was 104,000; for nine years in which rainfall was excessive the average mortality was 177,000. On examining the districts affected he found that in the West Punjab, where rainfall is scanty, "fulminant" malarial epidemic is very rare. In the south-east and sub-montane Punjab, such as Delhi, Amritsar, Gujranwala, and Gujrat, where rainfall is often heavy, the "fulminant" malaria epidemic often appears. He further found that its chief centres were the "riverain" districts (i.e., districts which have old beds of rivers) and also the flood lands along the banks of rivers from which the rainfall could not drain off quickly. In such places, where the country remained flooded for days, the "fulminant" type of malaria appeared most frequently. On the other hand, where drainage was good and the water did not remain standing for days, this "fulminant" malaria very rarely occurred. Thus the conclusion is clear, and I give it in Major Christophers's own words: "The removal or prevention of flood water in or near villages should be the first step in the sanitation of all rural districts." The same held good for the cities of Delhi and Amritsar, where flooding from river-beds and low-lying grounds near the city walls makes a dangerous state of affairs. Amritsar is nothing less than a water-logged city. The subsoil water is only three feet from the surface and the soil is clayey and the land flat. Thus malaria causes more deaths than plague, and it is sad to see the finest Indian peasants—the sturdy Punjabi—being ruthlessly decimated by malaria under the above conditions. It is useless to talk about mosquito destruction in some of these places, when quinine distribution and drainage are the

[1] This may be obtained from Messrs. Gulab Singh and Sons, Lahore, for 2 rupees.

two sanitary agents to push. In cities and villages, of course, small pools may be so treated, but these are often better filled up. There is another factor for which a remedy is harder to find, and that is scarcity of food. A year with short rains may be feverless, but if crops have no rain there is less food and higher prices. This lessened food-supply causes loss in stamina. Hence, if this is followed in the next year by a heavy monsoon (with large areas of mosquito breeding grounds) there will follow "fulminant" malaria. Better economic conditions alone can counteract this mortality. This would mean for the peasants a surplus from previous good harvests and freedom from debt. But those who understand how the Indian agriculturist is imposed upon by rich zemindars in the conditions on which he holds his land will be able to appreciate my remark that at present "better economic conditions" is but a dream. Government has started coöperative credit banks which deserve to be widely made known to the ignorant villagers. Major Christophers's conclusions may be briefly summarised as follows: 1. Economically "fulminant" malaria is by far the most important factor in the Punjab to be combated by sanitary and other measures. 2. There have been many "fulminant" epidemics in the Punjab in the past 50 years and with proper scientific measures these might be much lessened in the future. 3. The most salient feature of the epidemic is excessive mortality, especially among children. 4. These epidemics start from a centre or centres in every direction. At the centre is the heaviest mortality, sometimes rising to the weekly mortality of 500 per 1000 per annum. 5. The determining causes are excessive rainfall and food scarcity. The worst epidemics are apt to occur when a heavy monsoon succeeds a period of deficient rains. 6. The epidemic areas are not coincident with the heaviest rainfall areas, but with areas of floods. The drainage of flood waters is of first importance.

Lahore Medical College.

Major D. W. Sutherland, principal and professor of medicine, has just returned to India from deputation to England in connexion with the King Edward Memorial at Lahore, which is to take the form of very extensive improvements to this college and hospital.

Oct. 15th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Ninth Australasian Medical Congress.

THE Ninth Australasian Medical Congress assembled in Sydney on Monday, Sept. 18th, under the presidency of Dr. F. Antill Pockley. The delegates were formally welcomed on Saturday, the 16th, at the Town-hall, by the Lord Mayor of Sydney, Sir Allan Taylor. In the afternoon a reception was given at the University by the President and Mrs. Pockley. On Sunday special services were held at the Anglican and Roman Catholic Cathedrals, and at Stanmore Methodist Church. The Anglican Primate, Archbishop Wright, preached the sermon at St. Andrew's, and Archbishop Kelly officiated at St. Mary's. On Monday the business session was opened, and the committees on hospital abuse and contract practice abuse presented reports. In connexion with the latter, it was stated that the resolutions affirmed at the previous Congress as to a wage-limit clause being inserted in friendly societies' agreements had not been enforced in any State except New South Wales, where the professional organisation is very complete. The resolutions as to hospital abuse, agreed upon at former Congresses, were reaffirmed, with the addition that in the event of the financial support of the hospitals being undertaken by the Government patients able to obtain medical services outside the public hospitals should be excluded, and that in any event boards of management should be retained. The main purport of the reaffirmed resolutions was that no payment should be taken from patients in hospitals supported by Government grant or private benefaction, and that intermediate hospitals should be established, without staff, into which any practitioner might send patients under approved conditions and attend them there. Dr. R. Worrall, who introduced the report, spoke strongly against the proposals of the New South Wales Government for the nationalisation of hospitals, and the general feeling of Congress was entirely in sympathy with his attitude.

On Monday evening the Congress was formally opened by the Governor-General, Lord Denman, and Dr. Pockley delivered his inaugural address. The gathering was a very brilliant one, and distinguished representatives of all professions were present on the platform. The visitors were welcomed by the Premier of New South Wales and Sir Allan Taylor. Dr. Pockley's address dealt with various problems of medical science, and he expressed himself against the present socialistic trend of thought, which looked to nationalisation of medical service as a desirable ideal. On Tuesday work was begun in the various sections and proceeded throughout the week. The address in Surgery was delivered by Mr. G. A. Syme, of Melbourne, who reviewed the advance of modern surgical achievement, which he thought was not so extensive as was sometimes supposed, although operations were now much more safe than formerly and much more frequently undertaken. Mr. Syme dealt with his own personal experience of intra-thoracic surgery by means of tracheal insufflation and the great field of modern operation for appendicular and gall-stone affections. He also paid a high tribute to the achievements of two young Melbourne surgeons, Dr. T. P. Dunhill, in the surgery of the thyroid gland, and Dr. Basil Kilvington, in the resection of nerves for paralytic conditions. In the Section of Medicine Mr. W. T. Hayward, of Adelaide, delivered the presidential address, sketching the newer developments in medicine. At the same time he deprecated the fact that the modern student was overloaded in the attempt to keep pace with them. Mr. W. Beattie Smith, in the Neurological Section, pleaded for more accurate study of the causes of insanity. Mr. F. J. Clendinnen, in the Section of Radiology, and Mr. Herman F. Lawrence, in that of Dermatology, dealt chiefly with the action of radium in malignant disease. Both held that radium was of use in lessening the probability of recurrence, and should be used both in pre-operative and post-operative conditions. Dr. G. Rothwell Adam, in the Section of Gynæcology, and Dr. A. Jeffreys Wood, in that of Diseases of Children, reviewed recent work in its bearing on these special departments. In the Public Health Section Dr. B. Burnett Ham introduced a discussion on the Prophylaxis of Venereal Disease, and gave an outline of the work done in Melbourne, where a system of notification had been carried out for a year, supported by a Wassermann test in each reported instance. Of 5000 notifications some 1900 had given a positive reaction, and 400 a partial one. The whole of the testing was carried out by Dr. Konrad Hiller. Dr. Ham concluded with a series of proposals for the regulation of venereal disease. Chief among them were an impersonal notification; establishment of dispensaries open at night for gratuitous treatment; penalty for communication of venereal disease; segregation of dangerous cases; the suppression of solicitation and of impure literature, among other things. These things, he suggested, should be undertaken by the State. An educational campaign was also proposed in the form of a "Red Plague League," to be composed of men and women of all classes who should distribute literature and make known the dangers of venereal disease in other ways. Professor H. B. Allen strongly deprecated the teaching of sexual physiology in schools, as was sometimes advocated, which he thought would do more harm than good. Dr. Pockley held that such teaching would be beneficial.

At the final business meeting Dr. Dick's motion was adopted to establish a standing committee of Congress to watch medico-political events and report from time to time, such a committee to be representative of all States. Other resolutions of Congress called on the New Zealand and State Branches of the British Medical Association to enforce the clause passed at the last session of Congress, held in Melbourne in 1908, forbidding medical men to pass for professional attendance at contract rates any man whose income, together with that of his wife, exceeds £4 per week, or to attend any present member whose income, with that of his wife, exceeds £6 a week. To facilitate this, steps were recommended to be taken to strengthen the Australasian branch and to form a fund for those members who may suffer financially through such prohibition. The attention of Congress was also directed to the inadequate remuneration for club practice in some parts of Australia, and medical

men were forbidden to act as medical officers for proprietary aid or benefit societies unauthorised by the Standing Committee of Congress. The adoption of a *per capita* basis and not a fixed salary was also recommended.

In the Naval and Military Section resolutions declared inadequate the terms of service and pay of the Commonwealth Naval Medical School as at present outlined, and recommended the formation of a committee to discuss the subject with the Naval Board. The Section of Pathology, Bacteriology, and Tropical Medicine urged representations to the Federal Government to secure adequate funds and staff for the Australian Institute of Tropical Medicine. The Public Health Section passed resolutions dealing with feeble-minded children, the relationship to disease and the classification of Australian mosquitoes, the giving of death certificates, the formation of a central committee to deal with the collection of Australian medical data and statistics, the compulsory teaching of hygiene in State Schools and for older girls of the feeding and rearing of children, the detention of venereal prisoners for treatment, the compulsory notification of disease, and the treatment of venereal disease by non-qualified practitioners. The Sections of Neurology, Pathology, Public Health, and Diseases of Children urged the making of infantile paralysis compulsorily notifiable. The Section of Ophthalmology called for a proper course of technical instruction for spectacle-makers, demurred to legislation authorising opticians to test vision, and demanded the legal restriction of the term oculist to legally qualified medical practitioners. The next meeting of Congress was fixed for 1914, to be held in Auckland, N.Z., under the presidency of Dr. Arthur Purchas.

Friendly Societies Dispute.

An acute rupture has taken place between the medical men in Adelaide and the executive of the Adelaide United Friendly Societies Dispensary. Hitherto no dispensaries have existed in Adelaide, the lodge surgeons either dispensing their own medicines or having an arrangement with chemists, and charging a covering fee for such service. The lodge surgeons are of opinion that the proposed dispensary service does not offer a fair remuneration, and they object particularly to a scale of fees for operations in connexion with it. The outcome was that 83 medical men, comprising all the well-known Adelaide practitioners, issued a manifesto in the public press declining to accept the proposed terms. The Victorian branch of the British Medical Association passed a sympathetic resolution urging its members not to apply for the advertised positions. The Friendly Societies allege that they can fill the positions in spite of this opposition, and the matter remains for the present at this stage.

The Medical Service of the Federal Defence Scheme.

A disagreement has arisen between the Federal Defence Department and the medical profession over the remuneration to be paid for examination of cadets for the compulsory service scheme. The original arrangement was to pay area officers £25 for examinations within each area, but this was deemed inadequate, and the profession agreed to demand 2*s.* 6*d.* per head. To this the department disagreed, and proposes now a sum of £60 for area officers who would also be called upon to give certain attendance to the permanent staff within the area. The matter is not settled, but the department states an adjustment can probably be arrived at.

Oct. 4th.

THE AFTER-CARE ASSOCIATION.—Three meetings have recently been held on behalf of this society, whose objects are to assist poor persons discharged recovered from asylums for the insane. At Bath, through the kind invitation of Mrs. Blackburne, when the Archdeacon of Bath presided, and addresses were given by Dr. Maurice Craig, Dr. N. Lavers, and Mr. H. Thornhill Roxby. At Hampstead, at the kind invitation of Mr. and Mrs. Adair Roberts, Mr. Roberts presiding, short speeches explaining the work were made by Dr. Craig and Mr. Thornhill Roxby. At Bethlem Royal Hospital (by permission of the governors), Dr. Stoddart being in the chair, the audience was addressed by Alderman Sir William Dunn, Dr. G. H. Savage, Dr. J. Chambers, Dr. Robert Jones, the Rev. H. Stephens, and Mr. Thornhill Roxby. During the past year applications on behalf of 379 cases were received from various parts of the country.

Obituary.

SIR SAMUEL WILKS, BART., M.D. LOND., F.R.C.P. LOND., F.R.S.,

LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, AND CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

Samuel Wilks was born—as he himself has told us in his fascinating biographical reminiscences, reviewed in our columns only two weeks ago—at Camberwell on June 2nd, 1824. He was the second son of Joseph Barber Wilks, a cashier of the Honourable East India Company's service, a company which had claimed the life work of several of his ancestors. He received his early education at Aldenham Grammar School, Herts, and later at University College School. In 1840 he was apprenticed to Mr. Richard Prior, surgeon, of Newington, and attended at Guy's Hospital, matriculating also at the University of London. In 1847 he was admitted a Member of the Royal College of Surgeons of England, and took the M.B. of London University in the following year, graduating with honours in physiology and comparative anatomy, surgery, and medicine. In 1850 he took the M.D. degree at the same University, again with honours, and in 1851 became a Member of the Royal College of Physicians of London. He was elected to the Fellowship in 1856. He filled most of the offices of the College at various times, having been Examiner in 1867, Councillor in 1870 and again in 1880, Censor in 1875–76 and again in 1888, Vice-President in 1890, and President from 1896–99. In 1879 he delivered the Harveian Oration at the College, in which he laid stress on scientific investigation, in addition to the treatment of disease, as the daily task of the medical profession, and in happy vein contended that elevation of thought, imagination, poetry, and the love of the beautiful are no monopoly of literature and the fine arts, but belong equally to the pursuit of medicine and science.

In 1853 Dr. Wilks obtained the appointment of physician to the Surrey Dispensary. The prevalence of typhus fever in Bermondsey at that time afforded him the opportunity of studying that disease at first hand. Typhus had only recently been clearly distinguished by Sir William Jenner from typhoid fever, the two diseases having been previously confounded, under the common name of continued fever. Wilks's studies fully confirmed the correctness of Jenner's observations. He was for a year physician to the Infirmary for Children in Waterloo-road.

Wilks's connexion with Guy's Hospital was long and fruitful. After serving as medical and surgical registrar he became curator of the Museum, demonstrator of morbid anatomy, and subsequently lecturer on pathology, an appointment which he held for ten years—namely, until 1865. During this period he published the Pathological Catalogue of the Museum of Guy's Hospital, a valuable work of reference. In 1856 he was appointed assistant physician to Guy's Hospital. In 1865 he exchanged the lectureship on pathology for that on medicine, and in 1867 became full physician and continued to act in that capacity until 1885, when he was appointed to the consulting staff. For several years he edited the *Guy's Hospital Reports*, which have served him and the profession so good a turn in enabling him, in his recently published "Biographical Reminiscences," to recall and set forth methodically his own personal knowledge of many interesting developments of medicine recorded or illustrated therein. In 1864 Dr. Wilks was a member of the Contagious Diseases Commission, and later, 1870, of the Royal Commission on the Contagious Diseases Act. In 1867 he became examiner, and in 1885 a member of the Senate, of the University of London. He had previously, in 1868, held the post of examiner in medicine at the Royal College of Surgeons. In 1887 he became a Member of the General Medical Council.

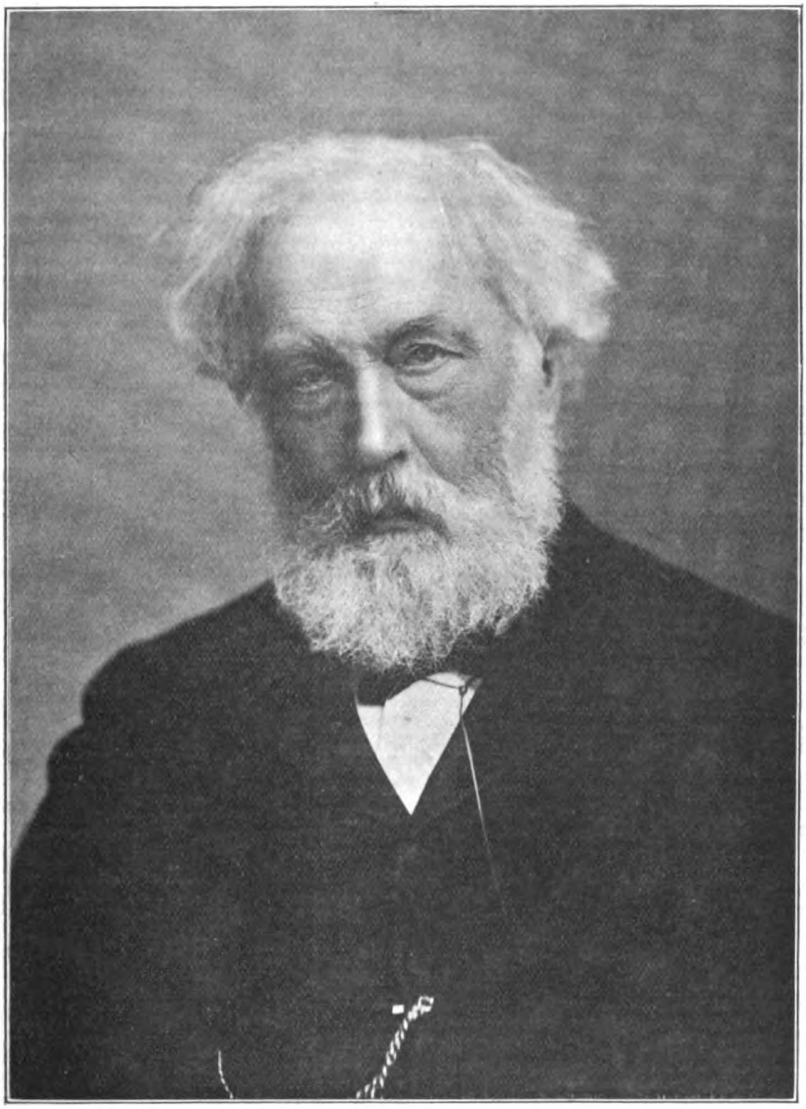
In 1870 Dr. Wilks was elected a Fellow of the Royal Society. In 1879 he was appointed physician to Their Royal Highnesses the Duke and Duchess of Connaught. In 1884 he received the honorary degree of LL.D. from the Edinburgh University. In 1897 he was created a baronet, and was honoured with the appointment of physician-extraordinary to Queen Victoria. In the same year he was awarded the Moxon gold medal, an honour conferred by the Royal College of Physicians of London on "the person who shall be deemed to

have most distinguished himself by observation and research in clinical medicine." In the following year, during his tenure of the Presidency of the College of Physicians, the memorable banquet to the medical profession was given at the Mansion House by the Lord Mayor, Colonel H. D. Davies, M.P. He also had the honour of admitting the late King Edward, then Prince of Wales, as an Honorary Fellow of the Royal College of Physicians. He retired from practice in 1904, and during the closing years of his life lived at Hampstead.

Of Sir Samuel Wilks's literary works the most important was the publication in book form, in 1859, of his lectures on Pathological Anatomy, which soon became out of print. In the preface the author stated that they contained no statement unverified by his own observation and experience. A second edition appeared in 1875, the work of preparation having been entrusted to Dr. Walter Moxon, who carefully retained the original character which was so great a feature of Wilks's work, and which caused "Wilks and Moxon" long to remain a standard textbook on pathology. The book reached a third edition. His lectures on Diseases of the Nervous System, published in 1878, had excited much interest at the time of their delivery, some ten years previously. In this work all the author's acquisitions from observation and reading were well digested and assimilated, and the description of disease was always accurate, though sometimes scanty, as was also the case in the matter of treatment. Besides the Pathological Catalogue of Guy's Hospital Museum, previously referred to, Sir Samuel Wilks published in 1892, in conjunction with Mr. G. T. Bettany, a biographical history of Guy's Hospital. Other works were his lectures on "Specific Fevers and Diseases of the Chest," published in 1874, and the article on Addison's Disease in Vol. V. of "Reynolds's System of Medicine" (1879). He also edited Addison's works, and his contributions materially helped to clear up some of the obscurity surrounding the pathology of Addison's disease. Besides occasional contributions to the medical press, some of his papers on Alcoholism and Vivisection were published in the *Contemporary Review* and the *Nineteenth Century*.

We have enumerated the many claims upon the recollection and gratitude of the medical profession that can be advanced for Sir Samuel Wilks; we append two eloquent personal appreciations of the great physician.

Dr. Hale White has sent us the following note on the career of his friend and master:—



"When Death came as a friend to Samuel Wilks he took with him a great man, one of those rare blessings to the human race who besides commanding our admiration for their intellect compel our affectionate reverence for their influence on us. He did not preach, but after talking with him you left him with a fresh incentive to work for its own sake and feeling that never would you be a party to any humbug, intellectual or other. It was his enthusiasm for scientific progress, his constant interest in the investigations of others, his encouragement to beginners, his honesty, his hearty contempt of dishonesty, and the way in which he exemplified that medicine was at its highest, not when it was a means of livelihood, but when it was an intellectual pursuit—it was all these points that made him loved by those who fell under his spell, that made young men determine to do their best, that led to delightful Sunday evenings at his house in Grosvenor-street, and later on to pleasant walks to see him at Hampstead. Twenty-seven years have passed since he ceased to be on the active staff of Guy's Hospital, but affection for him never waned, and many of his old pupils and friends have gone to Hampstead until the end, from time to time, to enjoy his company. He was a great talker, and as his good talk flowed on none noticed the flight of time. It might be that if you called on him about 3 you would find him smoking a cigar; this would go out as he talked, and at 4 two cups of coffee and some muffins would appear; these would all get cold, and when the talk ceased the cigar stump was relit, the cold coffee was drunk, and the cold muffins were eaten. His fine, beautiful face and his ironical sense of humour added to the charm of his company. Artists and sculptors innumerable have tried to reproduce his features—indeed, at one time he nicknamed himself the professional beauty, so frequent were these efforts.

"He often used to say that Guy's was his life; certainly no one has ever been more devoted to it or added more to its reputation. He was proud of its school, and, following his predecessors Bright and Addison, kept up its tradition that accurate and scientific observation should form the basis of medicine. To him the post-mortem room was as important as the ward, and his teaching has shown many hundreds of students that each case of disease is a problem to be unravelled, and in so doing has made their life's work a pleasure instead of a drudgery. It is 30 years since he gave up lecturing, and his lectures themselves were not, as far as I remember, especially attractive, but the matter was so good that the students begged him to reprint them; so those on 'The Specific Fevers and Diseases of the Chest' were published privately and could be bought at the hospital. Later on his 'Lectures on Diseases of the Nervous System' appeared and were eagerly read by his old pupils. As a teacher he rose above ordinary teaching, and you left him at the end of a round in the wards feeling not so much that you were richer in knowledge as that you had been taught how to use it, how to think, and that you had been inspired with an earnest desire to unravel problems for yourself and become a philosopher.

"Wilks was a great observer, but I am not now attempting to speak of his additions to medical knowledge which have made him famous. He was many-sided and always praised those who did thoroughly good work, even if he had no sympathy with it, and he had to an extraordinary degree the happy faculty of always being interested in something, provided it exercised his mind. He never lost this power until his final unconsciousness, and the way in which he exercised it to banish the tedium and loneliness of old age was wonderful. He was well read and fond of good literature. The photographs on his bedroom mantelpiece during his last illness were those of Wendell Holmes, Wordsworth, and Harriet Martineau. To the end he read his medical journals, and his interest in all kinds of knowledge made him one of the chief members of the Hampstead Scientific Society and gained him many friends among his neighbours. The longer you knew Wilks the more you loved and admired him, and only accident would lead to the discovery of his devotion to those of whom he was fond and his many generosities. As he got older the heroic fortitude with which without a murmur of complaint he put aside the suffering of his illness and drove it out of his thoughts by occupying them with reading, writing, and thinking, revealed a self-control that seemed well-nigh impossible. Not until the end came did the light of his mind cease to burn as bright, steady, beautiful, and clear as ever. To him, indeed, was the hackneyed phrase 'grand old man' applicable; he was a man who would have been a glory to any profession, and happily for us he chose that of medicine."

Yet another friend and colleague has sent us the following eloquent tribute to Wilks's merits as man and scientist:—

"With the death of Sir Samuel Wilks there passes out of the possession of Medicine a remarkable personality. He stands out as the one of all others in England who first set up pathology on its proper bedrock, by the careful record of his daily work in the post-mortem room of Guy's Hospital. His published lectures on Morbid Anatomy should thus ever remain a commanding monument to his memory, as we hope they will also ever be the pride of his school. For although that which a man sows is not that body that shall be, and even the morbid anatomy of one generation is not exactly that of the next, let the almost complete disappearance of 'pyæmia' and even infective disease, as Wilks saw them in his day, bear witness. The book is so carefully descriptive of the appearances of disease in all its aspects, as seen after death, that it must ever remain full of information for those who appeal to it. But what of the man himself? He was indeed a great man by the amount of enduring work that he did, and the amount of thought that he gave to it all, but he was possibly even greater by the unconscious power that was in him for gaining the affection of all his associates. Go anywhere one would, amongst his former pupils, and 'How is Wilks?'—it was, indeed, often more lovingly, if less reverently put—was sure to come. He was everywhere the subject of fond remembrance, and he had entwined himself into the very heart of Guy's Hospital in a way that looking back over 40 years, and into history beyond it, one may doubt whether any other man has ever done, unless it were Edward Carr or Arthur Durham. What was it that so endeared Wilks to his fellows? We might not all agree in this estimate, but three

SIR SAMUEL WILKS, BART., M D., F.R.C.P., LL.D., F.R.S.,
LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.
(Reproduced from a photograph by Messrs. Elliott and Fry.)

characteristics in chief seem to me to have determined it: his pride in Guy's Hospital; his inborn honesty; and his fund of rippling, gently cynical humour. There were plenty of other attractive features in him too. No man was more absolutely free of all self seeking; he was always too just himself. No one, I think, ever saw two sides to Wilks's character; he was always his own honest, kindly, humorous self. He was ever ready to help a struggling friend. One might think to read his character in great measure from his outward form—a somewhat loose figure and a decidedly non-martial gait. Although a close observer, he seemed to be always in thought. His fine head, his white hair, his long locks, the wondrous blue and twinkling eye that always seemed to illustrate the old proverb, "The mice are at play when the cat is away," in that it always seemed needing a special centre of control whilst he was carrying on some mental operations inside. He constantly gave one the impression of talking to you whilst being partly engaged elsewhere. I think he liked to follow his own train of thought rather than to discuss. There were therefore some who consulted him who were wont to think that he did not understand their case. The fact probably was that his range of its consideration was so wide that the particular symptom that commanded *their* attention did not particularly interest *him*. For a similar reason it would have been impossible to think of Wilks as a specialist. His mind ranged widely over the sick man himself to trace the order of his going. To him the study of mankind was man, and his outward form, the colour of his hair, the furrows on his nails, the condition of his skin, his mode of thought and speech, and so on, would lead him far afield into the hidden causes of things, and the origin of those grosser changes that he knew so well, and that had taught him so much in heaven and earth. Morbid anatomy, in setting him to ponder, had indeed taught him well, and his interests were manifold. The human mind, psychic force, the mental operations of his parrot, the origin of music, the nature of dreams, superstitions, furrows on the nails, scientific therapeutics, were a few of the many subjects which he handled, but the fads and fancies that so sadly beset too many of us he surely must have regarded with but a benevolent neutrality, as he was always for facts and did not care much about opinions.

"Of Wilks's veneration for Guy's Hospital no one can doubt when one reads the small volume published but a week or two ago under the kindly supervision of Sir Bryan Donkin. He was always ready to dwell upon the good work his school had done, and how it had ever been a pioneer along the road of medicine and surgery. This little book also shows the scrupulous regard he was wont to pay to the reputation of former workers in the various fields he traversed. Time and again he has been known to insist by speech and pen that in the matter of priority this or that one was in danger of being deprived of garments that of right belonged to him. Bright and Addison and Hodgkin and many another owe much to him and to his care that the work that he did should increase the stability of theirs; and so it was always to the very last. But it was perhaps in his familiar talks, in conversation, or the lecture theatre—for he still talked there—that he most of all appealed to his public, for there it was that his humour tumbled out in so unexpected and pleasant a way. Mr. Boyter Johnson, an old friend who knew him well, recalls that on rising to return thanks to his many hosts at the complimentary dinner to him on his being created a baronet, although greatly stirred by emotion, he commenced by saying that he had thought there were only two Samuels of repute—Samuel the Prophet and Sam Weller. Samuel Wilks had never occurred to him. There is another little specimen in his Reminiscences which one may extract. Speaking of alcoholic paralysis he says: 'Most of my examples were those of women, or, as I say, "ladies," for the patients were mostly wives of publicans and their husbands' landlords.' His shrewdness of observation may perhaps be indicated by the following episode, told also to Mr. Boyter Johnson. He was called one day to a noble mansion that excited his curiosity as to who the owner might be. He was unable to satisfy himself upon the point until, on leaving, the master of the house helped him on with his coat, and instead of the usual tug at the back that the footman gives he carefully adjusted it under the armpit. 'The man is a tailor,' said Wilks.

"One other characteristic may also well be recalled. He has been heard to say that most of his spare time was taken up by attending upon doctors and their families, and that it was always a matter of gratification to him that he was known as the doctors' doctor. Recollections of a man make but a poor picture, but they may suffice to show in barest outline how large-hearted a man our subject was, and, in some measure, why it was that he has passed away not only dear, to the last day of a ripe old age, to many friends and pupils—this might be the happy lot of a less manful and human spirit—but, to a depth beyond that, by all who knew him; he will have bidden farewell as he crossed the Bar with the hush of a most profound regard."

With these general expressions of esteem for the learning of Sir Samuel Wilks, and for the manly and stimulating qualities of his personality, we may be allowed to identify ourselves.

In 1854 Dr. Wilks married Elizabeth Ann, daughter of Henry Mockett, of Seaford, Sussex, and widow of his former preceptor, Mr. Richard Prior, M.R.C.S., of Newington. She died before him. Sir Samuel Wilks leaves no heir.

The funeral service was held in Hampstead Parish Church on Saturday, Nov. 11th. The body of Sir Samuel Wilks had been cremated that morning at Golder's Green, and the interment took place in Hampstead Cemetery. The chief mourners were Mrs. Allport (sister) and Mr. Ernest Wilks. The Royal College of Physicians of London was represented by Sir Thomas Barlow (President), Sir Dyce Duckworth, Dr. J. Mitchell Bruce, Dr. J. A. Ormerod, Dr. D. B. Lees, and Mr. W. Fleming; the Royal College of Surgeons of England by Mr. Rickman J. Godlee (President) and Mr. Clinton T. Dent (Vice-President); the Royal Society of Medicine by Sir Henry Morris and Mr. J. Y. W. MacAlister; the Governors of Guy's Hospital by Mr. H. Williams; the staff of Guy's Hospital by Dr. Frederick Taylor, Sir James Goodhart, Dr. G. H. Savage, Dr. Hale White, Dr. Newton Pitt, and Mr. Charters J. Symonds; and the Guy's Hospital Pupils' Physical Society by Mr. G. W. Goodhart. There were also present Sir William Osler, Sir John Rose Bradford, Sir William Bennett, Sir Shirley Murphy, Sir Bryan Donkin, Dr. E. F. Bashford, and the Mayor of Hampstead.

JOHN ALFRED COUTTS, M.B. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

Dr. J. A. Coutts, who died on Nov. 1st at Barnes, from pneumonia following influenza (as already stated), was the son of a prominent Tyneside shipbuilder, and was born in 1851. He was educated privately and at Emmanuel College, Cambridge, of which he was an exhibitioner. After graduating in the mathematical tripos he began to study medicine and entered St. George's Hospital. He qualified M.R.C.S. Eng. in 1881 and obtained the M.B. degree of his university in the following year. In 1884 he became a Member of the Royal College of Physicians of London, and in 1897 he was elected a Fellow. Dr. Coutts's long association with the East London Hospital for Children began in 1885 when he was appointed assistant physician; six years later he became full physician, and he held the latter post up to the time of his death. During his 26 years' work at Shadwell he became more and more identified with the study of pædiatrics, and established for himself a reputation as an excellent diagnostician and an authority on the literature of children's diseases.

In 1896 Dr. Coutts was Hunterian lecturer before the Royal College of Surgeons of England, and chose as the subject of his lectures "Some Aspects of Infantile Syphilis." He contributed several articles upon his special subject to Allchin's "Manual of Medicine" and to the "Encyclopædia Medica." He wrote well and often, but he seldom spoke in public. He was devoted to the East London Hospital, and his affection for it was returned by all who worked at Shadwell with him. His health was never strong, but he made the most of his physical powers, and throughout his life he was an enthusiastic student of athletics, being in particular a fine judge of rowing and oarsmanship. The news of his death after a very short illness came as a blow to his friends and patients, and his personality and work will long be remembered with affection.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are

announced:—Dr. P. Stuhr, professor of anatomy in the University of Würzburg.—Dr. Eyvin Wang, editor of the *Norsk Magazin for Lægevidenskaben*.—Dr. Alex. Hugh Ferguson, professor of clinical surgery in the Chicago College of Physicians and Surgeons.—Dr. Alfred Binet, director of the Laboratory of Experimental Psychology, Paris, aged 54.—Dr. Felix Löwenhardt, of Breslau, a surgeon well known for his operative ability in urinary diseases. He had been ill for a long period and unable to attend to his practice. His age was about 50.—Dr. R. Kroemer, director of the Conradstein Lunatic Asylum for West Prussia.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians on Oct. 26th, and of the Council of the Royal College of Surgeons on Nov. 9th, Diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the under-mentioned gentlemen, who have passed the Final Examination in medicine, surgery, and midwifery of the Conjoint Examining Board, and have complied with the respective by-laws. The following are the names of the successful candidates:—

John Wroth Adams, St. Bartholomew's Hospital; Thomas Ewart Ashley, St. Bartholomew's Hospital; Charles Nelson Atlee, St. Mary's Hospital; Cuthbert Hastings Attenborough, King's College Hospital; Cecil Crees Austen, Westminster Hospital; *John Bruce Baird, B.Sc., M.B., Ch.B. Glasg., Otago and Glasgow Universities and King's College Hospital; John Bramley Ball, L.D.S. Eng., Guy's Hospital; John Hamilton Barclay, M.B., B.S. Durh., Durham University; Howell Wood Barnes, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Robert Campbell Begg, M.A., B.Sc. New Zealand, New Zealaand and Edinburgh Universities; Thomas Mulholland Bellew, Liverpool University; Bertie Blackwood, Leeds University and Guy's Hospital; Gilbert Alan Blake, Guy's Hospital; Richard Frank Bolt, Bristol University; Howard Bullock, M.B., Ch.M. Sydney, Sydney and Oxford Universities and Middlesex Hospital; Maurice Burnett, King's College and St. George's Hospitals; Lionel Charles William Cane, Guy's Hospital; Herbert Edward Cockcroft, Manchester University; Harold Alexander Cooper, M.B., B.S. Durh., Durham University; John Lloyd Davies, University College Hospital; Hubert Daw, Guy's Hospital; Lionel Montrose Dawson, M.D., C.M. Queen's University, Kingston, Kingston University and London Hospital; Evan Richard Evans, St. Bartholomew's Hospital; George Douglas Gordon Fergusson, St. Mary's Hospital; Frederick Thomas Fisher, Birmingham University; Philip Stanley Foster, M.B., Ch.B. New Zealand, New Zealand University and London Hospital; Frank Garratt, University College, King's College, and St. George's Hospitals; Lister Gibbons, M.D. Buffalo, Buffalo University, London and St. Mary's Hospitals; Aubrey Scott Gillett, King's College Hospital; Ernest Franz Waldemar Grellier, Cambridge University and St. George's Hospital; James Bennett Hance, B.A. Cantab., Cambridge University and Guy's Hospital; *Robert Coltart Harkness, M.B., Ch.B. Edin., Edinburgh University; Walter Parker Harrison, L.D.S. Eng., Charing Cross Hospital; John Rippiner Heath, B.A. Cantab., Cambridge and Birmingham Universities; Ashley Ernest Herman, B.A. Cantab., Cambridge University and London Hospital; John William Wynne Hogan, Madras University and St. Bartholomew's Hospital; George Ashby Hooton, St. Bartholomew's Hospital; Abd El Aziz Ismail, M.D. Cairo, Cairo and St. Thomas's Hospital; Ah Chit Jap, Guy's Hospital; *Victor Stanley Kaufman, M.B. Toronto, Toronto University and London Hospital; Robert Kennon, M.B., Ch.B. Liverp., Liverpool University; George Eric Warner Lacey, Guy's Hospital; William Morgan Langdon, Guy's Hospital; †Ernest Millington Livesey, M.B., B.S. New Zealand, New Zealand University; David Charles Lloyd, Liverpool University and Guy's Hospital; George Carter Lowe, Guy's Hospital; Nagib Mahrus, Cairo and London Hospital; Charles Edward Hamilton Milner, King's College Hospital; Patrick John Monaghan, Guy's Hospital; Reginald Sperling Morshead, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Satyen Mozumder, St. Bartholomew's and Middlesex Hospitals; Marwood Mintern Munden, Guy's Hospital; William Marshall Oakden, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Bernard Rayne Parmiter, Guy's Hospital; Hugh Pierce, Liverpool University; Reginald Edward Porter, London Hospital; Thomas Conrad Reeves, London Hospital; *Henry Goulding Rice, B.A. Cantab., Cambridge University and Guy's Hospital; James Freer Richardson, London Hospital; Harrolde Bedford George Russell, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Wilfred Alan Russell, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Laurence Lancaster Satow, St. Bartholomew's Hospital; Henry Wakeman Scott, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Hew William Scott-Wilson, Oxford University and London Hospital; Ahmad Shafeek, Cairo and St. Thomas's Hospital; George William Shore, King's College Hospital; Thomas Henry Gostwyck Shore, Cambridge University and St. Bartholomew's Hospital; Alfred Bernard Pavey Smith, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Alan Richmond Snowdon, St. Bartholomew's Hospital; Harry Stobie, L.D.S. Eng., Charing Cross and St. Thomas's Hospitals; William Albert Stokes, B.A. Cantab., Cambridge and Birmingham Universities; Dudley Macaulay Stone, St. Mary's and St. Bartholomew's Hospitals; Elliott John Storer, St. Bartholomew's Hospital; James Llewellyn Montfort Symns, B.A. Cantab., Cambridge University and Guy's Hospital; Charles Joseph Gordon Taylor, B.A. Oxon., Oxford University and London Hospital; Julian Taylor, University College Hospital; John Wilson Tonks, B.A. Cantab., Cambridge University and University College Hospital; Percival Dillon Warburton, Sheffield University; John Wells Whiteman, Bristol University and Middlesex Hospital; John Helby Wilkinson, London Hospital; Thomas Davies Williams, London Hospital; James Ernest Studholme Wilson, London Hospital; Cecil Charles Worster-Drought, B.A. Cantab., Cambridge University and Guy's Hospital; and Frederick Cecil Wright, St. Bartholomew's Hospital.

* Diploma of M.R.C.S. previously conferred on Oct. 12th.

† Diploma of M.R.C.S. alone conferred.

The Council also conferred the Licence in Dental Surgery upon Donald Henry McDonald, Charing Cross and Royal Dental Hospitals, who has now complied with the by-laws for such licence.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Primary Examination for the Fellowship in Anatomy and Physiology held on Nov. 2nd, 3rd, 7th, 8th, 9th, and 10th, 127 candidates presented themselves, of whom 32 were approved and 95 were rejected. Among the successful candidates was one lady—Miss E. A. Ashby, of Birmingham University. The following are the names of the successful candidates:—

Gerald Graham Alderson, B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and University College and St. Thomas's Hospitals; Arthur Beeny Appleton, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Elizabeth Labrey Ashby, Birmingham University; Gerald Waddington Beresford, M.R.C.S., L.R.C.P., London Hospital; Edmund Boyd, B.A., M.B. Toronto, L.R.C.P., M.R.C.S., Toronto University and Middlesex Hospital; Gordon Normanby Brandon, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Robert Markham Carter, Captain I.M.S., M.R.C.S., L.R.C.P., D.T.M. Liverp., St. George's and King's College Hospitals; James Clark, M.D., Ch.B. Aberd., M.R.C.P., D.P.H., Aberdeen University and King's College; Raymond John Clausen, University College Hospital; Arthur Rawdon Carrington Doorly, St. Thomas's Hospital; Philip Geoffrey Doyne, B.A. Oxon., Oxford University and St. Thomas's Hospital; William Gilliatt, M.D., B.S. Lond., M.R.C.S., L.R.C.P., Middlesex Hospital; John Richard Griffith, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Thomas Sydney Shaw Holmes, M.B., B.Ch. Belfast, Belfast and London Hospital; Henry Julyan Hoyte, King's College; John Kennedy, M.D., B.S. Melb., Melbourne University and Middlesex Hospital; Henry Rylands Knowles, Leeds University; Archibald Campbell Magarey, M.B., B.S. Adelaide, M.R.C.S., L.R.C.P., Adelaide University and St. Mary's Hospital; Nanalal Maganlal Mehta, L.M.S. Bombay, Bombay University and Middlesex Hospital; Hubert Lewis Clifford Noel, M.R.C.S., L.R.C.P., London Hospital; Vernon Charles Pennell, B.A. Cantab., Cambridge University and St. Thomas's Hospital; John Lansdowne Perceval, Guy's Hospital; Maurice Nasmith Perrin, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Julian Lionel Priston, London Hospital; Martin Owen Raven, B.A. Oxon., Oxford University and St. Mary's Hospital; Henry Goulding Rice, B.A., B.C. Cantab., M.R.C.S., L.R.C.P., Cambridge University and Guy's Hospital; Walter Salisbury, Bristol University; Wilburn Smith, M.R.C.S., L.R.C.P., Jefferson Medical College and King's College; Arthur Hughes Southam, B.A. Oxon., Oxford and Manchester Universities and London Hospital; Harold Foster Strickland, M.R.C.S., L.R.C.P., L.D.S., Charing Cross and Middlesex Hospitals; Geoffrey Viner, M.D. Lond., St. Bartholomew's Hospital; and Ivan Stuart Wilson, M.D., M.B., Ch.B. New Zealand, M.R.C.S., L.R.C.P., New Zealand University and London Hospital.

At the First Professional Examination for the Licence in Dental Surgery held this month the following candidates were approved in the subjects indicated below:—

Mechanical Dentistry and Dental Metallurgy.—Arthur Wilfrid Adams, Bristol University; Leslie Alabone and Arthur James Barber, Guy's Hospital; Philip Blake, Royal Dental Hospital; Alfred Allwright Brown, William Allen Bulleid, Stephen Walter Coffin, and Louis Charles Cohen, Guy's Hospital; Walter Tyrrell Cooper, Royal Dental Hospital; Walter Alexander Crane, Liverpool University; George Lambert Cutts, Guy's Hospital; Arthur Thomas Dally, Royal Dental Hospital; Arnold Thomas Densham, M.A., B.C. Cantab., M.R.C.S., L.R.C.P., Guy's Hospital; James Douglas Dimock, Royal Dental Hospital; Ernest Francis Doubleday, Birmingham University; Cyril Henry Edwards, Guy's Hospital; Reginald Fox, Liverpool University; William Henry Churchill Gordon, Guy's Hospital; Percy Gordon Barlow Griffin, Liverpool University; Alan Basil Hacking and Arthur James Horniblow, Royal Dental Hospital; Philip Hutson, National Dental Hospital; Bernard Isaacs, Edward Eastaugh Johnson, Archibald Daniel Marston, Harry Millett, and Frederick Humble Morrell, Guy's Hospital; Harold Robert Parkes, Liverpool University; Edward Pitt, D.D.S. Pennsylvania, Pennsylvania University; Reginald Harry Rix, Guy's Hospital; Stephen Archibald Rodda, Royal Dental Hospital; Alan Filmer Rook and Ernest Charles Rycroft, Guy's Hospital; Thomas William Stark, Royal Dental Hospital; Cecil Ernest Thomas, Guy's Hospital; Harold Treleaven, Royal Dental Hospital; Percy James Wakley, Birmingham University; William Thomas Williams, Liverpool University; and Paul Bernard Wood, Royal Dental Hospital.

Mechanical Dentistry.—Sidney Adams, Guy's Hospital; Ronald William Anderson-Jardine and Carl William Reeves Bater, National Dental Hospital; Vincent Clifford Carrington, Sheffield University; Henry James Cavanagh, National Dental Hospital; Frederick Scott Cooper, Leeds University; William John Curtis, Royal

Dental Hospital; Wilfred Angel Easton, Guy's Hospital; Francis Malcolm Timothy Flintan, Royal Dental Hospital; John Langley Garrard and Walter Henry Glover, Guy's Hospital; Melville St. Clair Hamilton and Hubert Humphrey, Royal Dental Hospital; Aubrey Thomas Madin, Birmingham University; Arthur Helmuth John Miller, Royal Dental Hospital; Wallis John Milton, Bristol University; Norman Mulliner, Liverpool University; Gustavus Leigh Pemberton, Guy's Hospital; Alan Douglas Edward Shefford, National Dental Hospital; and Robert William Spong and Leonard Duncan Windemer, Guy's Hospital.

Dental Metallurgy.—Alexander Douglas Ball, Royal Dental Hospital; Harold Bridgwater Bramley, Liverpool University; Debenham Stuart Coombs and Frederick Andrew Craine, Royal Dental Hospital; Herbert James Edwards, Guy's Hospital; Frank Keith Hayman, Bristol University; Walter Owen Hughes, Liverpool University; Reginald John Inder, National Dental Hospital; Launcelot Machin, Guy's Hospital; Charles Wyndham Martin and Alan Edward Meeson, Liverpool University; Alan Lawrence Miller, Birmingham University; Frederick James Neal Guy's Hospital; Winifred Amelia Oaten, Royal Free and National Dental Hospitals; Clifford Thomas Plimsoll, Royal Dental Hospital; William Earle Starkey, Liverpool University; Stanley Stevens, Guy's Hospital; Norman David Swayne Straton, Royal Dental Hospital; Frederick Edward Alan Thorman, Birmingham University; and Thomas Huddlestone Urwin, Durham University.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Hagenbach-Burckhardt, Professor of Pædiatry, will retire at the close of the current winter session.—*Berlin:* Dr. Georg Axhausen has been appointed Oberarzt of the Surgical Clinic of the Charité, in succession to Dr. Pels Leusden.—*Bonn:* Dr. F. Heiderich, Extraordinary Professor in Göttingen, has been appointed Extraordinary Professor of Anatomy, in succession to Dr. Schiefferdecker. Dr. Alfred Machol, *privat-docent* of Surgery, and Dr. Hugo Selter, *privat-docent* of Hygiene, have been granted the title of Professor.—*Breslau:* Dr. Ludwig Tobler, of Heidelberg, has declined the offer of an Extraordinary Professorship at Bonn, but has been appointed to the chair of Pædiatry in Breslau, in succession to Dr. Freiherr von Pirquet, who is going to Vienna. Dr. J. Strasburger, *privat-docent* of Medicine in Bonn, has been appointed Extraordinary Professor of Medicine, in succession to the late Dr. R. Stern.—*Budapest:* Dr. Aladár Fischer has been appointed Surgical Primararzt in the Adele Bródy Children's Hospital, in succession to the late Dr. Jonas Baron.—*Burlington (University of Vermont):* Dr. F. U. Albee has been appointed to the chair of Orthopædic Surgery.—*Clausenburg (Koloswár):* Dr. Nikolaus Jancsó has been appointed to the chair of Medicine, in succession to Dr. S. Purjesz, retired.—*Dresden:* Dr. Kehrer, of Berne, has been appointed Director of the Obstetric and Gynæcological Clinic, in succession to the late Dr. Leopold.—*Greifswald:* Dr. Pels Leusden, of Berlin, has accepted the chair of Surgery, in succession to Dr. König.—*Grenoble:* Dr. Jacquemet has been appointed Professor of Medical Pathology.—*Innsbruck:* Dr. Hans Rabl, of Vienna, has accepted the chair of Histology in succession to the late Dr. Kerschner.—*Naples:* Dr. A. Bevacqua has been recognised as *privat-docent* of Pathological Anatomy.—*New Orleans (Tulane University):* Dr. Creighton Wellman has been appointed to the chair of Hygiene.—*Philadelphia (University of Pennsylvania):* Dr. Howard Fussell has been appointed Professor of Hygiene.—*Rouen:* Dr. Guerbet has been appointed Professor of Materia Medica.—*Stuttgart:* Dr. Heinrich Schmidt, assistant in the Medical Clinic at Tübingen, has been appointed Oberarzt of the Katherine Hospital.—*Toronto:* Dr. Graham has been appointed lecturer on Bacteriology.

THE MEDICAL PROFESSION AND MUNICIPAL HONOURS.—The following are the names of the medical men who have so far been announced as having been elected or re-elected to the headship of their corporations:—London: Sir Thomas B. Crosby, M.D. St. And., F.R.C.S Eng. (Lord Mayor). Barnstaple: Mr. J. R. Harper, M.R.C.S. Eng., L.R.C.P. Lond. Bolton: Mr. J. Young, M.R.C.S. Eng., L.R.C.P. Lond. Congleton: Mr. W. I. Fern, L.R.C.P. Irel., L.R.C.S. Edin. Exeter: Mr. C. J. Vlieland. M.D. Durh., M.R.C.S. Eng., L.S.A. Faversham: Mr. S. R. Alexander, M.D. Lond., M.R.C.S Eng., L.S.A. (re-elected). Hartlepool: Mr. W. S. Gibb, M.B., C.M. Edin. (re-elected). Hertford: Mr. J. Burnett Smith, M.B., C.M. Edin., L.R.C.P. & S. Edin., L.F.P.S. Glasg. Leamington: Mr. H. Mason, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond. (re-elected). Lewes: Mr. H. Stott, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Montgomery: Mr. N. W. Fairless-Humphreys, M.R.C.S. Eng., L.S.A. (re-elected). Newport (Mon.): Mr. J. McGinn, F.R.C.S. Irel., L.R.C.P. Edin., L.F.P.S. Glasg. Pwllheli: Mr. O. W. Griffith, L.R.C.P. & S. Edin. Saffron Walden: Mr. J. P. Atkinson, M.D. Glasg., L.R.C.P. Lond., L.R.C.S. Edin. (re-elected). Wallasey: Mr. J. Oldershaw, M.D. Brux., L.R.C.P. Irel., L.R.C.P. & S. Edin., L.F.P.S. Glasg. Warrington: Mr. C. W. Joseph, M.D. Durh., L.R.C.P. Irel., M.R.C.S. Eng., L.S.A. (re-elected). Wimbledon: Surgeon-Major E. L. McSheehy, A.M.D. (ret.), M.D., M.Ch. R.U.I., F.R.C.S. Irel.

Dr. William Arthur Brailey, consulting ophthalmic surgeon to Guy's Hospital, and a former Fellow of Downing College, has been elected to an honorary Fellowship at Downing College, Cambridge.

THE DEATH OF DR. W. P. MARSHALL.—We greatly regret to report the death of this young and promising physician under tragic circumstances. On the afternoon of Nov. 10th, Dr. Marshall was walking with his wife, to whom he had been married only a few months, across the swing bridge which spans the Ship Canal at Old Trafford. A heavy motor-lorry was crossing at the time, and for some unexplained cause it suddenly swerved and pinned Dr. Marshall against the iron framework of the bridge. The result was such serious internal injuries that he died in Salford Hospital three days later. Dr. Marshall was the only son of the president of the Baptist College, Rusholme, and he took his degrees in medicine three years ago at the University of Manchester.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general or quarterly meeting of this association will be held at 3 o'clock on Tuesday, Nov. 21st, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. W. R. Dawson. At 4 o'clock, during the same afternoon, the meeting will be resolved into a joint session with the Section of Obstetrics and Gynæcology of the Royal Society of Medicine (of which section Dr. Amand Routh is president), when a discussion will be invited upon a paper dealing with Amenorrhœal Insanity by Dr. C. T. Ewart. A paper by Dr. Geoffrey Clarke on Sterilisation from the Eugenic Standpoint will also be read and discussed. Members will subsequently dine together at the Café Monico Restaurant at 7 P.M. Cost of dinner 7*s.* 6*d.*, exclusive of wine. Evening dress optional. All communications should be made to Dr. C. Hubert Bond, honorary general secretary, 11, Chandos-street, Cavendish-square, London, W.

THE VAGRANCY QUESTION.—It is a matter of much gratification to the boards of guardians in Sussex that the vagrancy returns are showing a great decrease. The way-and-food ticket system was introduced into the county at the latter end of 1906, at which time Mr. J. S. Davy, who was then the Local Government Board inspector for the district, took great interest in it, but it was some years later ere the scheme became practically general throughout the county, Brighton coming in in 1909. The aims of the system are: (1) Assistance for the genuine workman in search of employment; (2) decrease in the number of professional beggars and habitual vagrants; (3) the support of the general public by informing them that there is no necessity for the indiscriminate giving of alms to wayfarers. As proof of the success of the system the Steyning Union, one of the largest unions in the county, provides some remarkable figures covering the year just completed. The number of vagrants dealt with at the workhouse of that union was 4810 in 1908, whereas the number in 1911 was only 1103 (898 men, 152 women, and 53 children). The way bills, bread and cheese tickets, and bread tickets diminished from 2180 to 508 in the same period. These figures show that the "in-and-outs" of our workhouses dislike the system and that they have been driven out of Sussex—into Surrey one guardian suggested at the recent board meeting. But why cannot the system become a general one all over the country? If it were so the tramping fraternity would soon find that their mode of life was receiving a very serious check everywhere, and not in a single district or districts, and that instead of the present administration of the Poor-law offering them encouragement in their habits it was proving to be an obstacle difficult of negotiation. The system is deserving of success because its working differentiates between the genuine working man and the real loafer.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The National Insurance Bill.

SEVERAL matters of deep interest to the medical profession were discussed by the House of Commons in connexion with the National Insurance Bill. As briefly recorded last week, the Government on Wednesday, Nov. 8th, brought forward amendments extending the size of the Local Health Committees and giving a preponderating representation on those committees to the Friendly Societies and the deposit contributors. Sir PHILIP MAGNUS made a vigorous protest against the change. He said that in the amendment which he had understood was accepted by the Chancellor of the Exchequer, the representation of the medical profession on the Health Committees was to have been 3 out of a maximum of 30. It had now been reduced without consultation with anyone to 3 out of a maximum of 80. He felt quite certain that the members of the medical profession would regard that as nothing less than the betrayal of their interests, and it certainly must be regarded, unless some explanation could be given, as a breach of faith. It was understood that part of the duties of the Health Committees would be to collect statistics of health conditions in the neighbourhood and to draw inferences from those conditions. That was not an easy matter, but it required some amount of scientific knowledge and experience.

Sir ROBERT FINLAY said that one of the points which the medical profession had always considered vital was that the control of the medical arrangements should not be committed to the Friendly Societies. It was arranged with the medical men that the control should not be with the Friendly Societies but with the Health Committees. The increase of the size of the Health Committee was simply part of an arrangement for, under another name, sending back the control of the medical arrangements to the Friendly Societies, from whom it was to be withdrawn.

Mr. LLOYD GEORGE, at a later stage, said that it was in the interests of the insured persons, of the medical men, and of every class of the community that there should be larger rather than smaller committees.

Mr. H. W. FORSTER: I do not suppose there would be any objection so long as the proportion which the doctors understood they were to have on the old committee is maintained.

Mr. LLOYD GEORGE: There was no question of proportion at all. The doctors asked for two and one, but nothing was said about proportion.

Sir ROBERT FINLAY at a later stage remarked that it was a vital point with the doctors that the control of the medical benefit should not rest with the Friendly Societies, and it had been understood that that was conceded by the Chancellor of the Exchequer.

Mr. LLOYD GEORGE: Does the right honourable gentleman say that I agreed with the medical profession that the Government should not give a majority on the Local Health Committee to approved societies?

Sir ROBERT FINLAY: That is another point altogether. What I was saying was that the Chancellor of the Exchequer was understood to have agreed with the medical profession that the control of medical benefit should not rest with the Friendly Societies. If I am wrong I will be glad to be corrected.

Mr. LLOYD GEORGE: It is important that there should be no possible mistake about this. What I did agree to and what is now provided by the Bill as amended was that the Local Health Committee should have the control of medical benefit save in existing rights. That is already incorporated in the Bill. I certainly never agreed to anything but that the majority of the committee should be elected by the insured persons.

Sir ROBERT FINLAY: The right honourable gentleman has really not in any way qualified what I have said. I do not think that he has made it all clear. What I said was—and the fact remains uncontradicted—that the right honourable gentleman agreed with the medical men that the control of the medical benefit should not rest with the Friendly Societies but with the Health Committees. We are now told that medical benefit should not rest with Friendly Societies but with a majority of the Health Committee representing insured persons. That is precisely the same thing.

Mr. LLOYD GEORGE: This is a question which involves, if I may say so, a matter of faith between the medical profession and myself. What I understood the right honourable gentleman to say was that I agreed that the control of medical benefit was to be left to the Local Health Committee and not the Friendly Societies. I want to make it clear that that did not involve, as the right honourable gentleman now puts it, that I agreed that the control should be with the Local Health Committee and not the majority of the insured persons.

Sir ROBERT FINLAY: The right honourable gentleman propitiated a great many medical men who thought the pledge would be observed in the spirit as well as the letter. Now it turns out that by manipulation of the Health Committee the control is to be given to the insured persons—namely, the Friendly Societies and the deposit contributors

Mr. LLOYD GEORGE: Does the right honourable gentleman sugges that a breach of faith is involved in giving a majority on the committee to the insured persons? If he does, will he quote a single note or any statement made to a responsible medical man in which I said that the control was to be given to the Local Health Committee without having regard to the majority of insured persons being represented?

Sir ROBERT FINLAY: The right honourable gentleman certainly never told the medical men that such a change as this was going to be made in the constitution of the Health Committee, and if he had told them they would not have been so satisfied as they were at the time. What I do say was that this change vitally alters the conditions on which the medical men were disposed to be satisfied with what the right honourable gentleman said. The right honourable gentleman has transformed at the last moment the composition of the Health Committee. He has transformed it by increasing the number to 80 from 22, and whereas the medical men were necessarily to have 2 out of the 22, out of this maximum of 80, which the amendment proposes, they are entitled necessarily only to 3. That is a totally different state of things from what the medical men thought they had got. The fact that an amendment of this kind was in contemplation ought to have been revealed to the medical profession when they accepted the statements of the Chancellor of the Exchequer. The truth is that the Chancellor thinks he has made his peace with the Friendly Societies and at the expense of the medical representatives who had trusted to what they understood he said. I make no apology for referring to this matter at some little length, because the cooperation of the medical men is absolutely essential to the working of this Bill. I am very much mistaken if the feeling in the profession is not that in this matter it has not been treated fairly.

Dr. C. ADDISON said that the version of the right honourable gentleman, the Member for Edinburgh and St. Andrews Universities (Sir ROBERT FINLAY), had been given somewhat under a misapprehension. The medical men fully realised that the representatives of insured persons should be in a majority on these committees, and they never, so far as he knew, at any time demurred to that proposition. What they were anxious for was that their case should be properly and fairly stated before these committees. So far as that went, he quite recognised that the alteration of the numbers of the committees did make a very material difference in the position as it stood originally and when the arrangement was originally made. The medical men believed that their case was strong enough to stand its ground, but they were anxious that it should be considered without prejudice as far as possible, and as this amendment introduced a material alteration he would ask the Chancellor of the Exchequer to assure the House that, so far as the precise numbers were concerned, he did not commit himself finally, but would leave it open for representations to be made before the report stage to see whether the profession was satisfied with this alteration, which perhaps it had not yet had full opportunity to consider. The medical profession was perfectly satisfied that it had a good case. All that he wanted was to have it fairly stated, and he would ask the right honourable gentleman, in view of the altered circumstances, to give the profession an opportunity of making representations before the report stage if it wished to do so.

The clause was amended in the terms indicated in THE LANCET of Nov. 11th.

It was also agreed to make provision for the appointment of auxiliary Health Committees. It is now laid down in the clause that the regulations made by the Insurance Commissioners "shall require the Local Health Committee of every county (except in cases where, owing to special circumstances, the Commissioners consider it unnecessary) within six months after the commencement of this Act to prepare and submit for approval to the Commissioners a scheme for the appointment of an auxiliary committee for the county and prescribing the area to be assigned to each such committee, and in particular the scheme shall provide for the appointment of an auxiliary committee for each borough (including the City of London and a metropolitan borough) within the county having a population of not less than ten thousand, and for each urban district within the county with a population of twenty thousand, unless the Local Health Committee consider it expedient in the case of any such borough or urban district that there should not be a separate auxiliary committee for the borough or urban district, or that any adjoining areas should be grouped with such borough or urban district for the purpose of the appointment of an auxiliary committee." Clause 44 (Powers and Duties of Local Health Committees) was passed without discussion under the closure resolution.

The Excessive Sickness Clause.

Some interesting speeches were delivered on Thursday, Nov. 9th, when Clause 46, which deals with excessive sickness in a locality, was considered. The object of the section is to throw upon local authorities, house owners, and employers the liability to make good the cost of excessive sickness in a district attributable to bad housing, insanitary conditions, or contaminated or insufficient water-supply. A general debate took place on the question whether the approved Societies and Local Health Committees should have their powers limited to insurance matters so far as possible or whether they should have power over Local Government matters.

The Chancellor of the Exchequer made a very spirited defence of the

proposals of the clause. He contended that it set up machinery not for interfering with the local authorities, but to enable the societies which were damnified by the inaction, the illegal action, or the neglect of authorities, owners, or employers, to carry out the provisions of the law. What were the main complaints of the Friendly Societies with regard to the extra causes of ill-health which added to their expenditure? They were bad drainage, bad water-supply, bad housing, factories not in accordance with the conditions of the law. The offenders were local authorities and private individuals. There had been years of Public Health Acts in this country and local government inquiries without number. There had been recommendations of medical officers of health and inspectors of the Local Government Board. He was able to prove that they were absolutely helpless in hundreds of cases and had been so for years, not because the Local Government Board had neglected its duty. It was purely because it was armed with the clumsiest, rustiest weapon in the whole armoury of British law—the *mandamus*, a perfectly worthless weapon. He would read to the House an extract from the pen of the chief medical officer of the Local Government Board in his review for the year 1909. He said: "A story of neglect of elementary sanitary work outstands in a large proportion of the current reports by medical inspectors of the Board on local sanitary circumstances. A not inconsiderable number of the smaller towns and urban districts and many of the rural districts which have within their area portions presenting urban characteristics are characterised by continuance, more or less, of the filth nuisances which were fairly general 50 years ago, but which have since then been abolished in the larger and better governed towns."

If anyone would go through these reports, Mr. LLOYD GEORGE continued, he would find that there were local authorities by the score which never prosecuted offenders against the Public Health Act, which kept no records and never even investigated insanitary conditions, which had no sanitary committee, which systematically refused to carry out the recommendations of their sanitary officials, which had in force neither by-laws nor adoptive Acts, and which neglected to apply such by-laws and Acts when adopted. So far from interfering with any existing authorities, he simply proposed to assist them to put the law in force. The clause would be of enormous value to the Local Government Board. Instead of threatening to issue a *mandamus* it would be able to say to a local authority, "Well, if there is an epidemic you will be mulcted in damages." The clause would be a help to county councils, who had general supervision over health all over the country. It would be of enormous benefit to the medical officers of health of counties, who were practically powerless. All that they could do was to expose the evil. Their position was a very difficult one. They had often to report upon insanitary conditions when the proprietors of the properties were strongly represented on these councils. He had a letter last week from a medical officer of health who gave his name and address. He said to him: "It is as much as my place is worth to report faithfully on the conditions prevailing." So far from causing overlapping and weakening, the clause was a source of strength. He wanted to make insanitary property and neglect of public duties unremunerative.

Some doubt was afterwards expressed whether the Chancellor of the Exchequer was adopting the best method to deal with authorities and persons who neglected to enforce sanitary laws. One suggestion was to the effect that in cases of default the county council should have power to enter and do the necessary work. Another was to increase the powers of the Local Government Board.

However, the clause was carried, after the introduction of some amendments. Owing to its importance the essential part of it may be reproduced in its amended form. It is as follows:—

"1. Where it is alleged by the Insurance Commissioners or by any approved society or Local Health Committee that the sickness which has taken place among any insured persons being, in the case where the allegation is made by a society or committee, persons for the administration of whose sickness and disablement benefits the society or committee is responsible, is excessive, and that such excess is due to the conditions or nature of employment of such persons, or to bad housing or insanitary conditions in any locality, or to a defective or contaminated water-supply, or to the neglect on the part of any person or authority to observe or enforce the provisions of any Act relating to the health of workers in factories, workshops, mines, quarries, or other industries, or relating to public health, or the housing of the working classes, or any regulations made under any such Act, or to observe or enforce any public health precautions, the Commissioners or the society or committee making such allegation may send to the person or authority alleged to be in default a claim for the payment of the amount or any extra expenditure alleged to have been incurred by reason of such cause as aforesaid, and if the Commissioners, society, or committee and such person or authority fail to arrive at any agreement on the subject may apply to the Secretary of State or the Local Government Board, as the case may require, for an inquiry, and thereupon the Secretary of State or Local Government Board may appoint a competent person to hold an inquiry.

2. If upon such inquiry being held it is proved to the satisfaction of the persons holding the inquiry that the amount of such sickness has—(i) during a period of not less than three years before the date of the inquiry; or (ii) if there has been an outbreak of any epidemic, endemic, or infectious disease, during any less period—been in excess of the average expectation of sickness by more than 10 per cent., and that such excess was in whole or in part due to any such cause as aforesaid, the amount of any extra expenditure found by the person holding the inquiry to have been incurred under this part of this Act by any societies or committees where the allegation is made by the Insurance Commissioners, or if the allegation is made by a society or committee, by the society or committee in question, by reason of such cause shall be ordered by him to be made good in accordance with the following provisions: (*a*) where the excess of such part thereof as aforesaid is due to the conditions or nature of the employment or to any neglect on the part of any employer to observe or enforce any such Act or regulation as aforesaid, it shall be made good by the employer; (*b*) where such excess or such part thereof as aforesaid is due to bad housing or insanitary conditions in the locality, or to any neglect on the part of any local authority to observe or enforce any such Act or regulation as aforesaid, it shall be made good by such local authority as appears to the person holding the inquiry to have been in default; or if due to the insanitary condition of any particular premises shall be made good by the owner or occupier of the premises who is proved to the satisfaction of the person holding the inquiry to be responsible; (*c*) where the excess or such part thereof as aforesaid is due to an insufficient or contaminated water-supply it shall be made good by the local authority or company by which the water is supplied, or which having imposed upon it the duty of affording a water-supply has refused or neglected to do so, unless the local authority or company prove that such insufficiency or contamination was not due to any default on the part of the authority or company, but arose from circumstances over which it had no control."

There are several other subsections of the clause, but they relate to procedure and machinery.

Sanatoriums.

Clause 47, which relates to the erection of sanatoriums, was also passed with several amendments. On the motion of Mr. LLOYD GEORGE words were inserted to enable county councils to manage and maintain sanatoriums (as well as to erect them as provided by the clause), and for that purpose to make arrangements with Local Insurance Committees and other authorities. It was also agreed to insert the following new subsection: "A Local Health Committee may, with the consent of the Insurance Commissioners, enter into agreements with any person or authority that, in consideration of such person or authority providing treatment in a sanatorium or other institution or otherwise for persons recommended by the committee for sanatorium benefit, the committee will contribute out of the funds available for sanatorium benefit towards the maintenance of the institution or provision of such treatment, such annual or other payment, and subject to such conditions and for such periods as may be agreed, and any such agreement shall be binding on the committee and their successors, and any sums payable by the committee thereunder may be paid by the Insurance Commissioners and deducted from the sums payable to the committee for the purposes of sanatorium benefit."

Scotland and the National Insurance Bill.

As the result of the amendment of the clause applying the National Insurance Bill to Scotland, a separate National Insurance Commission is to be set up for that country and also a national fund. County councils have been given the power to set up approved societies in districts where no organisation of the kind exists Local Health Committees have also been given power to modify or suspend certain benefits and give their equivalent in other benefits in districts where the conditions render this course advisable. Several honourable Members spoke in appreciation of the work of medical men in the remote Highlands and Islands of Scotland. It was suggested that a mileage rate should be paid to them. The Chancellor of the Exchequer recognised the importance of this problem, but pointed out that the amended clause might permit arrangements to be made in favour of these medical men.

Ireland and the National Insurance Bill.

Extensive changes have been introduced into Clause 59 of the National Insurance Bill (which applies the measure to Ireland). There is to be a separate insurance fund for Ireland, and a separate Insurance Commission will be set up for that country. Medical benefits have been eliminated from the Bill so far as it affects Ireland, and certain modifications have been introduced into the constitution of the Local Health Committees. The debate on the Irish clause extended over Tuesday, Nov. 14th, and Wednesday, Nov. 15th. On the latter day Mr. LLOYD GEORGE moved a long amendment, a portion of which was to the following effect:—"An insured person in Ireland shall not be entitled to medical benefit under this part of this Act, and the provisions with respect to medical benefit shall not apply; Provided that medical benefit for an insured person being a member of an approved society shall be deemed to be included amongst the additional benefits specified in Part II. of the Fourth Schedule to this Act." The excision of the medical benefit was accompanied by a diminution of contributions.

In some quarters of the House some misgivings were expressed at the decision to remove the medical benefit from Ireland. Mr. DILLON

for instance, admitted that whilst public opinion in that country was in favour of excision of medical benefit, he hoped that the day was close at hand when it would be adopted. Mr. BIRRELL, the Chief Secretary to the Lord Lieutenant, spoke in a somewhat similar strain. He described to the House the conditions under which the poorer classes in Ireland received medical attendance from the dispensary doctors. These gentlemen, 810 in number, received a salary averaging about £160 or £170 per annum, but they had also the right of private practice. Last year 479,644 cases were attended to by these medical men at the dispensaries and 163,115 cases at the private houses of the patients, and the cost of the service, which fell about equally on the rates and the local taxation fund, was £193,153. Personally he regretted that the medical benefit was to be struck out of the Bill in favour of the retention of the dispensary system, but he thought that public opinion in Ireland was already veering round on this question. He hoped as time went on that the dispensary system might be removed and the salaries of these medical men largely increased by their being able to come under the Bill on some reasonable basis. The right honourable gentleman acknowledged the excellent work done by the dispensary doctors, whom he characterised as "as decent and kind-hearted a set of men as were to be found in the United Kingdom."

Sir JOHN LONSDALE asked the Chief Secretary whether these medical men would receive a fee for furnishing such medical certificates as might be necessary for the purposes of the administration of the benefits still to be given under the Bill. Mr. BIRRELL replied that the dispensary doctor would be entitled to the same fee as any other medical man.

Dr. C. ADDISON, whilst he admitted that the change was being made in response to opinion in Ireland, deplored the step. He pointed to the very large number of uncertified deaths in that country as evidence that great improvement in the organisation of medical aid was to be desired. The present system could not, in his view, lead to the prevention of disease in the same way as the Bill with medical benefit in it would do. Sick pay and medical benefit were as a scientific arrangement inseparably associated. A vital objection to the excision of medical benefit in Ireland was that the ultimate success of the scheme depended on the development of preventive medicine. Sir E. CARSON suggested that the question of medical benefits for Ireland should be made the subject of further consideration.

The Chancellor of the Exchequer stated that he regretted leaving out medical benefit for Ireland, but the change was being made in deference to the wishes of the people in that country. However, if there was a feeling in Ireland that medical benefit should be included in the Bill he would not resist it on behalf of the Government. The matter was not an actuarial question, but was one of bargaining with the medical profession. He did not find that the Irish medical men were easier to bargain with than the English. If the Members from Ireland could make some arrangement with the medical profession in that country he would not resist a proposal to recommit the Bill in regard to the question of the medical benefit. Mr. M. HEALY, intervening, suggested that an option might be given to districts to adopt the medical benefit, but Mr. LLOYD GEORGE put aside the suggestion on the ground that it would be fatal to the finance of the Bill. He was inclined to agree, he proceeded to say, that eventually Ireland would come in for the whole of the benefits. What he thought would happen would be this. A great many workmen in Ireland objected to going to dispensary doctors because they thought that their action in doing so carried a suspicion of pauperism. He was told that that was the case in respect to the Belfast and Cork workmen. He anticipated that such workmen would join societies which for an increased contribution gave medical benefit. But they would lose the employer's contribution. Members from Ireland would then press Parliament for an extension of the full benefits to their country. Sir JOHN LONSDALE asked the Chancellor to consider the advisability of granting superannuation allowances to dispensary doctors who had reached the age of 65, but the Chairman ruled that that question did not arise under the amendment. After some further discussion the Chancellor's amendment was agreed to, and the clause as amended was passed.

The Rag Flock Bill.

The Rag Flock Bill has been read a second time in the Commons and committed to a committee of the whole House.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 8TH.

Colonial Chemists and British Registration.

Mr. KELLAWAY asked the Secretary to the Treasury whether he was aware that the negotiations between the council of the Pharmaceutical Society of Great Britain and the colonial representatives with a view to formulating a by-law providing for the admission to the Register of Chemists of persons holding colonial certificates of qualification equivalent to the British qualification had now been in progress for about three years; whether he had any reason to suppose that these negotiations would be completed by the time the National Insurance Bill became operative; and, if not, how he proposed to prevent chemists holding colonial certificates, and who were now in business in this country, being excluded from the lists of chemists qualified to dispense medicines under the Bill.—Mr. MCKINNON WOOD replied: I am aware of the fact stated in the first part of the question. I am unable at present to say when the negotiations will be completed or what alternative plan may be adopted in the event of their proving abortive, but the honourable Member may rest assured that the matter will not be lost sight of.

Mr. GLYN-JONES: Is the right honourable gentleman aware that such a by-law has been passed at three meetings of the Council of the Pharmaceutical Society, and that at the last meeting, held a week ago, a by-law providing for the recognition of colonial certificates was passed for the first time?—Mr. MCKINNON WOOD: I have been informed on good authority that that is the case.

Chinese Pork.

Mr. FELL asked the President of the Local Government Board when the report of the inspector employed to inquire into the conditions of the production of pork in China would be published.—Mr. BURNS answered: The report has been published and I am sending the honourable Member a copy of it.

Industrial Fatal Accidents.

Mr. ARTHUR HENDERSON asked the Secretary of State for the Home Department whether he could give the number of fatal accidents in places under the Factory Acts during the first nine months of 1911 and the corresponding period of 1910; also the number of cases of lead poisoning and other industrial diseases reported to the Home Office inspectors during the same periods.—Mr. MCKENNA said in reply: The figures asked for are as follows:—Fatal accidents in the first nine months of 1910, 780; in the first nine months of 1911, 819; cases of industrial poisoning in the same periods—in 1910, 412; in 1911, 560.

THURSDAY, NOV. 9TH.

Parliamentary Inquiry into Patent Medicines.

Mr. C. BATHURST asked the Secretary of State for the Home Department whether he was aware that the yield of stamp duty in respect of patent medicines during the year ended March 31st last was £325,646, which was an increase of £12,532 on the receipts from this source for the previous year; and whether, in view of the present consumption by poor persons of worthless concoctions of this description possessing no curative properties, he would, without further delay, introduce legislation dealing with the matter.—Mr. MCKENNA replied: I agree with the view of my predecessor that the subject of the conditions of the sale of patent medicines might usefully be considered by a Select Committee next session. I do not understand the honourable Member to suggest that all patent medicines are worthless concoctions.

The Teeth of School Children.

Baron DE FOREST asked the President of the Board of Education whether, in view of the condition of affairs set forth in the report of the chief medical officer of the Board, he would require every local education committee to provide for the regular inspection, by a properly qualified dental surgeon, of the teeth of the children under its care.—Mr. PEASE said in reply: I do not think that there is any necessity at present to place dental inspection on a different basis from other parts of the medical and physical examination of the child. Examination of the mouth, including the teeth, is made in all cases by the school medical officer and his medical assistants. In a number of areas dentists have also been appointed to aid the school medical officer in this part of the work, which the Board is carefully watching. The Board does not think it advisable at the present moment to place the additional burden suggested by the honourable Member upon local authorities.

Health at Osborne College.

Lord CHARLES BERESFORD asked the Civil Lord of the Admiralty whether there had been many cases of blood poisoning at Osborne College; and, if so, whether these cases had occurred through the foulness of the river Medina owing to the sewers running into it near the Kingston workshops.—Mr. LAMBERT answered: There have been only two cases among cadets at Osborne College which could be described as "blood poisoning" since the College was opened in 1903. There is no evidence to connect either with the condition of the river Medina.

Hospital Surgeons and National Insurance.

Sir PHILIP MAGNUS asked the Chancellor of the Exchequer whether a physician or surgeon in receipt of a salary, on account of his services to a hospital, of £50 a year, but whose professional income exceeded £1000 a year, came under the compulsory insurance clauses of the National Insurance Bill.—Mr. LLOYD GEORGE replied: The answer is in the negative.

Vaccination of Children.

Mr. LANSBURY asked the President of the Local Government Board whether his attention had been called to the fact that at an inquest held at Leigh on two children who died about 13 days after vaccination with Government lymph, it was stated that the recommendations of the Local Government Board were that Poor-law children should be vaccinated within seven days from birth; whether these recommendations were made by the Local Government Board; and, if not, whether he would consider the desirability of informing all Poor-law medical officers of the present views of the Board in the matter of vaccinating workhouse children at such an early age.—Mr. BURNS wrote in reply: The Local Government Board has made no recommendation to the effect suggested. It has always held the view expressed by the Royal Commission on Vaccination that, although under favourable conditions vaccination may be carried out within a few days of birth, the practice is to be deprecated unless there is at the time obvious danger of small-pox contagion, or unless the parent specially requests that the operation may be performed. My medical inspectors have been instructed to communicate this view to boards of guardians and their officers when needful, and I do not think it necessary to make any general communication to Poor-law medical officers on this subject.

The Advisory Committee to the Insurance Commissioners.

Dr. ADDISON asked the Chancellor of the Exchequer whether it was his intention that at least one of the women members of the Advisory Committee to the Insurance Commissioners should be a registered midwife. Mr. LLOYD GEORGE furnished the following reply: The answer is in the affirmative.

MONDAY, NOV. 13TH.

The Teeth of School Children.

Baron DE FOREST asked the President of the Board of Education whether he was aware that, at the centres in London where dental treatment had been provided for children attending council schools, it

had been found at an early stage to be necessary to supplement the work of the school doctors by special dental inspections; whether he had any information showing that the incidental examination of the teeth in the course of the ordinary medical inspection was any more adequate in other areas; and whether, in view of the experience of these London centres and of the condition of affairs revealed by the report of the chief medical officer of the Board, he would reconsider his decision that there was no necessity to insist upon a special dental inspection.—Mr. PEASE said in reply: The answer to the first part of the question is in the affirmative. With regard to the second part, the examination of teeth varies in degree and character in different areas. With regard to the last part, I am fully alive to the importance of this matter, but I am unable to add anything at present to my answer to the honourable Member's question on the subject on Nov. 9th.

Proposed Sanatorium at Abergele.

Sir HERBERT ROBERTS asked the President of the Local Government Board whether he had considered the practically unanimous representations made by the ratepayers of Abergele and by the Abergele urban district council and other local bodies, supported by the medical officer of health of the county of Denbigh, against the acquisition by the South Manchester board of guardians of Plas Ucha, Abergele, for the purpose of a sanatorium; and whether, in view of the evidence as to the injury which the establishment of a sanatorium would inflict upon Abergele as a residental neighbourhood and summer resort, he could postpone his decision as to the Order until consideration had been given to the proposals under the Insurance Bill for conferring upon local authorities special powers of joint action in respect of the erection of sanatoriums and the distribution of sanatorium benefits.—Mr. BURNS answered: I have given very careful consideration to this matter from every point of view, and I have come to the conclusion that, subject to the observance of certain conditions, assent should be given to the proposal of the guardians. I have sent to my honourable friend a copy of the letter I have addressed to the guardians on the subject.

Royal Army Medical Corps.

Mr. BENNETT-GOLDNEY asked the Financial Secretary to the War Office what was the present shortage of the Royal Army Medical Corps, of all ranks, in the Regular Army, in the Reserve, and in the Territorial Force; at the last three examinations of candidates for commissions in the Royal Army Medical Corps had the numbers of those who had duly qualified exceeded the number of vacancies; and how many candidates were there at present for existing vacancies in the commissioned ranks of the Royal Army Medical Corps.—Mr. TENNANT replied: The present shortage is as follows:—

	Officers.	Other ranks.
Regulars	22	208
Reserves	—	3174
Territorial Force	283	1759

There is no definite establishment of officers of the Special Reserve, but the present strength amounts to 114. At the last three examinations for commissions the numbers of candidates qualified exceeded the number of vacancies. For the examination to be held next January for not less than 20 vacancies, three candidates have already entered, but the list will not be closed until Jan. 15th.

Royal Naval Medical Service.

Mr. BENNETT-GOLDNEY asked the Secretary to the Admiralty whether he would state if the shortage of medical officers in the Royal Naval Medical Service at the present time was less than it was 12 months ago, and what was the shortage according to the last available figures in all grades, from inspector-general down to the junior surgeons.—Mr. MACNAMARA said in reply: The shortage is practically the same as it was 12 months ago—20 have entered and 22 have gone, owing to retirements or deaths. The shortage is 60 of all ranks.

Mr. BENNETT-GOLDNEY asked the honourable gentleman what were the names of the service and other members of the Consultative Board of the Royal Naval Medical Service; whether this committee had hitherto been habitually called together to carry out the work entrusted to it during the customary working hours of the Admiralty staff, or had it been called together on an officially appointed early closing day and after normal closing hours; and at what hour did this committee meet now and on what day.—Mr. MACNAMARA answered: The names of the members of the Medical Consultative Board are as follows: President: the Medical Director-General of the Navy. Civilian members: Sir W. Watson Cheyne, Sir Dyce Duckworth, and Professor W. J. R. Simpson; naval member, Surgeon-General Howard Todd; and secretary, Fleet-Surgeon James L. Smith. The Admiralty has no officially appointed early closing day. The Medical Consultative Board is called together when occasion arises, and usually meets about 5 P.M., as that hour has been ascertained to be most convenient for the civilian members irrespective of Admiralty working hours. There are no routine meetings. Meetings take place as and when found necessary.

TUESDAY, NOV. 14TH.

Conscientious Objections in Scotland.

Mr. WILKIE asked the Lord Advocate whether he could state the total number of declarations of conscientious objection to vaccination made in Scotland in the years 1907, 1908, 1909, and 1910; and whether he could also give the percentages of these declarations to births.—Mr. URE replied: The information desired by my honourable friend for the years 1907, 1908, and 1909 is as follows:—

Year.	No. of births registered.	Declarations of conscientious objections to vaccination.	
		No.	Percentage.
1907	128,891	7,258	5·631
1908	131,406	15,846	12·059
1909	128,720	22,746	17·671
Total	389,017	45,850	11·786

The corresponding information for 1910 is not yet available.

Plague in India.

Mr. KEIR HARDIE asked the Under Secretary of State for India what special measures, if any, were adopted for dealing with the plague in and around Delhi; or whether he could say to what he attributed the practical disappearance of the plague from that district.—Mr. MONTAGU replied: In the Delhi district the ordinary measures for dealing with plague have been applied. The freedom of the district from plague during the third quarter of the year is not unusual. In 1910 no case was reported from July 1st up to the third week of September. This year the whole of the Punjab from July up to date has been exceptionally free from plague.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BOAL, J. G., M.B., Ch.B. Edin., has been appointed House Surgeon at the West Kent General Hospital, Maidstone.

BUSHNELL, F. G., M.D., B.S. Lond., D.P.H., has been appointed Deputy School Medical Officer to the West Sussex Education Committee.

EVANS, DOUGLAS GORDON, M.B., B.S. Lond., has been appointed Medical Superintendent of the Children's Memorial Hospital, Cedar Avenue, Montreal, Canada.

HAMER, W. H., M.D. Cantab., F.R.C.P. Lond., M.R.C.S. Eng., D.P.H., has been appointed Medical Officer of Health and School Medical Officer for the County of London.

HILEY, R. MELVILLE, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the Royal Hospital for Diseases of the Chest.

JONES, EDITH A., M.B., B.S. Lond., has been appointed Assistant School Medical Officer to the Swansea Education Committee.

MACARTNEY, DUNCAN, M.B., M.Ch. Glasg., has been appointed Full Visiting Surgeon of the Western Infirmary, Glasgow.

MCEWEN, J. D., M.B., B.Ch. Edin., has been appointed House Physician and Casualty Officer at the Walsall and District Hospital.

O'NEILL, JAMES J., M.B., B.Ch., B.A.O. R.U.I., has been appointed House Surgeon at the Carnarvonshire and Anglesey Infirmary.

PINTO-LEITE, HUBERT, M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the London Throat Hospital.

TODD, F. R., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at the West Kent General Hospital, Maidstone.

WALLACE, JOHN, M.B., C.M. Edin., has been appointed Medical Officer of Health and Medical Superintendent of the Isolation Hospital by the Weston-super-Mare (Somerset) Urban District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £100 per annum, all found.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Second Anæsthetist.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 per annum, with board and washing.

BIRMINGHAM CITY ASYLUM, Winson Green.—Junior Assistant Medical Officer. Salary £150 per annum, with board, laundry, &c.

BRENTFORD UNION INFIRMARY.—Second Assistant to the Medical Superintendent, unmarried. Salary £125 per annum, with apartments, rations, washing, &c.

BRIGHTON, ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road.—House Surgeon for six months. Salary at rate of £80 per annum, with board, lodging, and washing.

BRISTOL, COSSHAM MEMORIAL HOSPITAL, Kingswood.—House Surgeon. Salary £50 per annum, with board, lodging, and washing.

BRISTOL ROYAL INFIRMARY.—House Physician. Salary £100 per annum, with board, apartments, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CARDIFF, KING EDWARD VII.'S HOSPITAL.—Three Honorary Assistant Anæsthetists.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—Resident House Surgeon. Salary £50 per annum, with board and residence. Also Registrars and Clinical Assistants.

COLCHESTER EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

DERBY, COUNTY BOROUGH OF.—Assistant Medical Officer of Health. Salary £140 per annum, with board and residence.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Assistant Physician.

FLEETWOOD, ROSSALL SCHOOL.—Resident Medical Officer, unmarried. Salary £250 per annum, with board and residence.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £70 per annum, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Physician to Out-patients. Also Surgeon to Out-patients. Also Medical Registrar. Salary £127 10s. per annum. Also House Surgeon for six months. Salary £30, with board, residence, and washing.

HULL ROYAL INFIRMARY.—Assistant House Surgeon. Salary at rate of £60 per annum, with board and lodging.

INDIAN MEDICAL SERVICE.—Twelve Commissions.

KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Vacancy on the Honorary Medical Staff.

LICHFIELD, BURNTWOOD COUNTY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, and washing.
LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.
LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Resident Medical Officer. Salary £250 per annum, with board and residence.
LONDON HOSPITAL DENTAL SCHOOL.—Two House Anæsthetists. Salary £40.
LONDON LOCK HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.
LONDON TEMPERANCE HOSPITAL.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing.
MAIDSTONE, WEST KENT GENERAL HOSPITAL.—House Surgeon and Assistant House Surgeon, both unmarried. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.
MANCHESTER CHILDREN'S HOSPITAL (OUT-PATIENTS' DEPARTMENT), Gartside-street, Manchester.—Medical Officer. Salary £180 per annum.
MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing.
MANCHESTER ROYAL EYE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with residence, board and washing.
MANCHESTER, ST. MARY'S HOSPITALS FOR WOMEN AND CHILDREN—Two House Surgeons. Salary at rate of £50 per annum, with board and residence.
NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing.
OXFORD UNIVERSITY.—Readership in Pharmacology.
PORTSMOUTH, MUNICIPAL TUBERCULIN DISPENSARY.—Assistant Medical Officer. Salary at rate of £250 per annum.
POWICK, WORCESTER COUNTY AND CITY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £180 per annum and all found.
PRESTON, COUNTY ASYLUM, Whittingham.—Pathologist and Assistant Medical Officer. Salary £200 per annum, with board, apartments, and washing.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Surgeon-in-Charge of Out-patient Department for Ear, Nose, and Throat.
RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board and apartments.
ROYAL BERKSHIRE HOSPITAL.—Second House Surgeon. Salary £60 per annum, with board, lodging, and washing.
ROYAL COLLEGE OF PHYSICIANS.—Milroy Lecturer for 1913.
ROYAL DENTAL HOSPITAL OF LONDON, Leicester-square.—Morning House Anæsthetist. Salary £25 per annum.
ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Honorary Ophthalmic Surgeon. Also Honorary Dental Surgeon.
ST. THOMAS'S HOSPITAL.—Resident Assistant Physician. Also Surgical Registrar.
SCARBOROUGH HOSPITAL AND DISPENSARY.—Junior House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.
SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £60 per annum, with board, lodging, and washing.
SUNDERLAND CHILDREN'S HOSPITAL.—Resident Medical Officer. Salary £80 per annum, with board, residence, and laundry.
THROAT HOSPITAL, Golden-square, W.—Honorary Assistant Surgeon.
TRURO, ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with rooms, board, and washing.
UNIVERSITY OF LONDON.—Examiners.
WEST LONDON HOSPITAL, Hammersmith, W.—House Physician for six months. Board, lodging, and laundry allowance.
WIGTON, COUNTY OF.—Medical Officer for the Medical Inspection and Supervision of School Children. Salary £250 per annum, with travelling expenses.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE.—On Nov. 12th, at All Saints Green, Norwich, the wife of Hamilton A. Ballance M.S. Lond., F.R.C.S. Eng., of a son.
CLARKE.—On Nov. 5th, at Amphill, Reading, the wife of Fielding Clarke, M.R.C.S. Eng., L.R.C.P. Lond., &c., of a daughter.
GABB.—On Nov. 7th, at Cornwallis-gardens, Hastings, the wife of Harry Gabb, B.A., M.B., B.C., of a son.
LAING.—On Nov. 13th, at Husbands Bosworth, Rugby, the wife of G. D. Laing, M.D., of a son.
O'FLAHERTY.—On Nov. 9th, at Mount Edgcumbe-terrace, Stoke, Devonport, the wife of A. R. O'Flaherty, Major, R.A.M.C., of a son.
WORTHINGTON.—On Nov. 7th, at Nuwara Eiliya, Ceylon, the wife of Captain Frank Worthington, R.A.M.C., of a daughter.

MARRIAGES.

MACKINNON—ROWELL.—On Nov. 11th, at St. Paul's Church, Upper Norwood, Murdoch Mackinnon, M.D., D.P.H., Medical Registrar of Seamen's Hospital, Greenwich, to Isabella Irvine (Lily), third daughter of the late David Rowell and Mrs. Rowell, of Wallington Lodge, Upper Norwood.

DEATHS.

BUCKELL.—On Nov. 11th, Francis John Buckell, M.B., B.S., aged 67 years.
NEATBY.—On Nov. 12th, at Brookfield, Highgate, Thomas Neatby, M.D., aged 76 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND CRIME OF CYPRUS.

ACCORDING to the Cyprus Blue Book for the year ending March 31st, 1911, the general health and sanitary condition of the island have been most satisfactory. There was no serious outbreak of infectious or contagious disease until the conclusion of the year, when an outbreak of small-pox occurred, which was kept in check by vigorous measures of isolation and energetic vaccination. Plague still menaced the island as in previous years, and the outbreak of cholera in neighbouring countries caused anxiety, but fortunately the island escaped both these serious dangers. A marked reduction took place in the number of cases of cerebro-spinal meningitis, only 84 patients, as against 1000 in the previous year, being mentioned in the returns. The cases showed a milder form of infection, and there is every indication that the disease has assumed a sporadic form. Malarial fever was less prevalent than in former years, 6074 cases being returned, against 7450 in 1909 and 10,476 in 1908. The people are beginning to recognise the value of the various prophylactic measures recommended; the use of mosquito nets, improved sanitation, and quinine is becoming more general. The hospitals of the island show an all-round increase in attendance and admissions. The total number of in-patients treated at the Government Central Hospital at Nicosia and the five district-aided hospitals was 2201, with 125 deaths (5·67 per cent.). The out-patient departments were also well attended; the patients numbering 23,859. 298 surgical operations were performed, to which must be added 316 minor operations among out-patients. The Central Hospital, the only purely Government hospital in the island, had a most successful year. The beds now number 53 and provide accommodation for men, women, and children. There are wards for the treatment of poor and paying patients. Medical, surgical, eye, and isolation beds now exist, and the general utility of the hospital is improving year by year. Nearly 200 surgical operations were performed at this hospital alone, and patients from all parts of the island received the skilful and careful attention of an efficient and well-trained medical and nursing staff. In all the other district hospitals also advancements and important improvements have been made; among these the Larnaca Hospital, built from funds raised by private effort and in great measure supported in the same manner, is noteworthy. The number of in-patients treated during the year was 232 and of out-patients 3603. Useful structural additions have been made and an English nurse's services have been secured in place of those of a native. The hospital is well equipped as regards beds, bedding, instruments, and other arrangements for the comfort of patients. The returns of the 12 rural medical officers show that 10,461 patients were treated by them. The services of these officers are much appreciated by the inhabitants of the more remote towns and villages of the island.

At the close of the year the inmates of the leper farm numbered 99. Their lot has been considerably relieved by a substantial increase in the grant allowed them by Government. Each year, on account of the extension of the Government Medical Service and the increasing number of medical practitioners, fewer cases of the disease escape notice and segregation. One child was admitted to the home, there being now 11 of both sexes thus removed from the farm, and it is interesting to report that in no case so far has any sign of the disease appeared. The education of these children is receiving attention, and they are being taught trades. A lunatic asylum is being built outside Nicosia, and it is hoped that it will be completed next year. Twenty cases of insanity were admitted to the lunatic wards of the hospitals during the past year; six inmates died, 20 were sufficiently recovered to be released to the care of relatives or friends, and at the end of the year 56 patients remained under treatment. Vaccination, although not compulsory, was extensively carried out. Fresh imported glycerinated vaccine was the medium used. 6332 of these operations were carried out; 6197 were primary vaccinations. It is difficult to over estimate the value to the island of the work carried out by the analyst at the Government laboratory. Under the head of criminal investigation 240 samples were examined, chiefly relating to murder and poison cases, and expert evidence was given by the Government analyst in many criminal trials.

In the section of the report devoted to "Crime and Criminal Statistics" the following passage occurs: "The most disquieting feature is the increase in the number of cases of murder and manslaughter." In commenting upon this unsatisfactory feature the Chief Justice brings to notice some interesting traits in the character of the villager which tend to account to some extent for the prevalence of this class of crime. The majority of the inhabitants of Cyprus live in villages and are as a rule poor, while their habitations are for the most part comfortless and insanitary. Their pursuits are almost entirely pastoral or agricultural. These people are very sensitive and ready to take offence. Any insult

rankles, and their minds seem to brood over any slight, real or imaginary, however small, until it has assumed proportions which, for their self-esteem, they consider they must revenge by murder. Conversely there are men in some of these villages who for no personal reason whatever, but solely in response to a small reward, say £10, will murder a man against whom they have no grievance or whom they have never seen before. In many cases if an inhabitant is obnoxious to the community they will have him killed by common agreement. They are very quick-tempered and many homicides occur in brawls in cafés and at weddings where men are under the influence of drink. Without reflection a knife is drawn and their natural impulse is to kill. "I have tried many murderers in this island," writes the Chief Justice, "and I cannot recall one who was sorry for his victim or showed remorse for his crime. As a rule, a murderer boasts of his crime. It is a source of pride to himself and gives him power over his neighbours." There are many ways, both direct and indirect, of dealing with such a state of affairs in a community where life appears to be held so lightly. Religion and education both have their part to play and are complementary rather than antagonistic to repressive measures. The legislature declines to pass any law effectually enabling the carrying of dagger-knives to be suppressed and strongly opposes any prohibition of carrying firearms. Small punishments are not likely to stop the practice. It is a question how far heavy penalties are desirable. In the case of intentional killing without premeditation the only punishment is 15 years under the Ottoman Penal Code, and the term has been practically cut down to 11 years and 3 months by the rules made for the remission of sentences. There is a large volume of evidence to show that the passions and jealousies raised at elections are the direct or indirect cause of many of the crimes of violence.

THE DANGER OF USING ELECTRICAL BED-WARMERS.

To the Editor of THE LANCET.

SIR,—Whilst in no way being desirous of exaggerating the danger of fire from electrical contrivances intended to minister to the comfort of modern man, I think that at this season a word of warning should be addressed to the many elderly people and invalids who are being fascinated by the handy and practical advantages of electrical bed-warmers—i.e., the substitute for the hot-water bottle, and which are intended to retain heat as long as they are attached to the local electrical supply service. These electrical bed-warmers are extremely dangerous, as they easily ignite when kept under cover in such a manner as not to freely radiate heat—i.e., if kept tightly covered under bedclothes or the like. I have before me the remains of one of these appliances, well devised and attractively made, recently purchased by a medical man for the use of a lady. After use of about three hours on the 240 volt circuit of one of our London electrical supply companies the bed-warmer ignited the bedclothes, and it was entirely a matter of chance that the user escaped with her life owing to the heat created by the smouldering bedclothes waking her before asphyxiation. I have since tried several similar appliances purchased in the open market on a 110 volt current, and I have not so far found one that can be described as free from danger. I trust this timely word of warning at this season may be the prevention of unnecessary deaths from fire.

I am, Sir, yours faithfully,

Nov. 10th, 1911. CAVE.

POOR CHILDREN'S YULE TIDE ASSOCIATION.

To the Editor of THE LANCET.

SIR,—The work of the Poor Children's Yule Tide Association has my very heartiest sympathy, and I desire to commend it to all readers of your columns as deserving of support. By means of this association the poor little slum lasses and lads of our city have each the certainty of a real Christmas gift, and those to whom this season annually brings numerous presents can hardly understand the joy of these unfortunate little ones at being remembered by Santa Claus in this kindly way. Last year there were 103 Christmas-trees and 30,000 toys distributed by the association in 321 of the poorest districts of London. This year we not only wish to do as well, but to reach even a larger number than before, in order that not one little child shall be left out of the distribution.

Christmas comes but once a year, and only once a year is this appeal made. While busy with one's own plans for the festive season, it is but fitting that a thought hould be spared for the many toyless and joyless little bairns of our streets. Subscriptions should be sent to the Hon. Sec., Poor Children's Yule Tide Association, 32, John-street, Theobalds-road, W.C. I am, Sir, yours faithfully,

Hyde Park Barracks, S.W., Nov. 10th, 1911. COMPTON.

A NEW ORDNANCE MAP.

Mr. Edward Stanford, official agent for the large-scale ordnance maps, announces the publication of the first 165 sheets of a new issue on the scale of 50 inches to a mile (1:1250). Hitherto, apart from the town plans, the largest scale on which urban districts have been obtainable has been the well-known 25 inches to a mile, and the new issue is based on an enlargement of that map. The larger scale map has been specially prepared for use primarily in connexion with land valuation, and the area covered by each sheet is one quarter of that of a 25-inch sheet. The size of the sheets is 40 × 27 inches, and the price 2*s.* 6*d.* each. The sheets already issued deal with various districts in Cheshire, Durham, Hampshire, Lancashire, Leicestershire, Northumberland, Sussex, and Yorkshire. They may be inspected at Mr. Stanford's Geographical Establishment, 12, 13, & 14, Long-acre, W.C.

THE BRITISH MEDICAL MAN ABROAD: TURKEY.

To the Editor of THE LANCET.

SIR,—When recently turning over your last Students' Number I observed the statement on p. 656 under this title: "It has not yet happened that a European physician failed to pass the colloquium." This, I fear, is not correct. Unfortunately a medical missionary of this society—M.D., Ch.B. Dub.—failed to pass in December, 1909. The actual examination was really nothing, the gentleman being asked to enumerate the varieties of abscesses found in the liver, their treatment, diagnosis, symptoms, &c., and the symptoms, diagnosis, and treatment of dysentery. Various conjectures were made by Constantinople friends as to the reason, and whether it was due (1) to the fact that his name had a termination which in the Turkish mind suggested the possibility of his being an Armenian; (2) in order to show the authority of the examiners that they were not bound to pass all applicants; (3) or whether "nerves" and "French" were in any way responsible (the doctor admitted being very nervous), the fact remains that he was "ploughed." I thought you would probably be glad to be corrected on this point. I might perhaps add that he was not permitted to sit a second time for the colloquium.

I am, Sir, yours faithfully,

SAML. W. W. WITTY.

Church Missionary Society, Salisbury-square, E.C.,
Nov. 8th, 1911.

J. C. H. L.—The "wonderful specific," according to our analysis, contains chalk, menthol, and sugar, but no alkaloid.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for the next few months:—

September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Nov. 10th–25th (Manchester).—Smoke Abatement Exhibition.
,, 21st–23rd (Montreal).—Canadian Public Health Association (First Annual Meeting).
November (Rome).—Fourth International Congress of Physical Education.
Dec. 4th–9th (Havana, Cuba).—American Public Health Association.
,, 19th–23rd (Moscow).—Third Pan-Russian Therapeutical Congress.

In 1912:—

Jan. 20th–27th (Hong-Kong).—Second Biennial Congress of the Far Eastern Association of Tropical Medicine.
March 23rd–April 4th (London, Royal Agricultural Hall).—International Smoke Abatement Exhibition.
,, (London).—First Congress of Pure Food and Health Society of Great Britain.
,, (Berlin).—Thirty-third Balneological Congress.
April 1st–7th (Tunis).—Twenty-second Congress of French-speaking Alienists and Neurologists.
,, 14th–20th (Rome).—Seventh International Congress on Tuberculosis.
,, (Rome).—Seventh International Congress of Dermatology and Syphilology.
,, (Giessen).—Congress on Study of Families, Inheritance, and Race Hygiene.
Spring (London).—Second Optical Convention.

The following journals, magazines, &c., have been received:—

Archives Générales de Médecine, Dublin Journal of Medical Science, Archives Internationales de Neurologie, Archives de Médecine et de Pharmacie Militaires, Magazine of the London (Royal Free Hospital) School of Medicine for Women, Bulletins et Mémoires de la Société de Radiologie Médicale de Paris, Revue de Gynécologie, Folia Therapeutica, Quarterly Journal of Experimental Physiology, Jahrbuch für Kinderheilkunde und Physische Erziehung, St. Paul Medical Journal, International Journal of Surgery, Journal of the Royal Institute of Public Health, Aesculapae, Archivos Españoles de Neurologia, Psiquiatria y Fisioterapia, Indian Medical Record, Indian Medical Journal, Local Government Chronicle, Ash's Monthly, Military Surgeon.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

TUESDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—J. H. Targett, W. W. H. Tate), at 4 P.M.

JOINT MEETING with the MEDICO-PSYCHOLOGICAL ASSOCIATION, at 11, Chandos-street, W.

Discussion:
Amenorrhœal Insanity (opened by Dr. C. T. Ewart).

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—H. Charles Cameron, H. H. Dale): at 4.30 P.M.

Papers:
Dr. F. Ransom: The Effects of Adrenalin.
Dr. A. R. Jordan: Urinary Antiseptics

PATHOLOGICAL SECTION (Hon. Secretaries—J. C. G. Ledingham, A. E. Boycott): at 8.30 P.M.

Dr. W. Langdon Brown: The Bundle of His from a Case of Heart-block (with specimens and lantern slides).
Dr. A. E. Boycott: Sahli's Hæmoglobinometer.
Dr. H. Priestley: The Differentiation of the Diphtheroid Group of Organisms.
Dr. H. R. Dean: Further Experiments on Complement-fixation and Precipitation.
Dr. J. Henderson-Smith: Some Experiments on Lysis.
Dr. J. C. G. Ledingham: Some Experiments on Phagocytosis regarded as an Adsorption Phenomenon.

THURSDAY.

NEUROLOGICAL SECTION (Hon. Secretaries—Wilfred Harris, T. Grainger Stewart): at 8.30 P.M.

Dr. Boyer: Systematic Examination of the Central Nervous System in a Case of Obstetrical Paralysis.
Mr. Sydney Mann: Method of Colouring Brains to Demonstrate Cortical Localisation and Arterial Supply, for Teaching Purposes.
Dr. F. W. Mott, F.R.S.: Colour Photographs of Microscopic Specimens of the Nervous System.
Dr. Lind: Experimental Lead Poisoning (Sir Thomas Oliver). Examination of the Brains of Two Animals.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—T. R. Whipham, H. S. Clogg, Percy G. Lewis), at 11, Chandos-street, W.: at 4.30 P.M.

Cases:
Dr. Vincent Dickinson: Infantilism.
Dr. R. H. Miller: (1) Chronic Interstitial Nephritis with Infantilism; (2) Intracranial Tumour.
Mr. D. C. L. Fitzwilliams: Cases to Illustrate his Paper.
Dr. F. J. Poynton: Psoriasis and Flexion of the Terminal Phalanx of the Thumb.
Dr. A. C. D. Firth: A Family (Mother and Three Children) showing Congenital Absence of the Patella and Deformities of the Nails.
Dr. R. S. Trevor and Dr. H. D. Rolleston: Pathological Specimen—Cerebral Aplasia and Hydrocephalus.

Papers:
Dr. H. D. Rolleston and Dr. J. B. Molony: Purpura in Acute Infective Diarrhœa of Infants.
Mr. D. C. L. Fitzwilliams: Congenital Flexion of the First Interphalangeal Joints of the Fingers.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Paper:
Dr. Sandilands: Small-pox in London, 1885 to 1935.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Adjourned Discussion on the Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System. Speakers:—Sir Victor Horsley, Dr. R. Russell, Dr. T. B. Hyslop, Major French, R.A.M.C., Dr. W. Harris, Dr. F. Buzzard, and Mr. A. Fleming.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

TUESDAY.—3 P.M., Dr. G. Clarke: Sterilisation from the Eugenic Standpoint.—Dr. C. T. Ewart: Amenorrhœal Insanity.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Dr. C. G. Grant: The Sydney Street Affair from its Medico-Legal Aspect.

CHELSEA CLINICAL SOCIETY, St. George's Hospital Medical School, S.W.

TUESDAY.—8.30 P.M., Dr. A. G. Buchanan: Psycho-therapy. A Discussion will follow.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Dr. W. M. Ettles: Some Recent Developments in Ophthalmic Therapeutics.—Dr. H. R. Andrews: Pyelo-nephritis in Pregnancy.—Dr. Langdon Brown: A Brief Appreciation of Hughlings Jackson's Work.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—Dr. J. Taylor: Early Signs and Symptoms of Nervous Disease.—Mr. D. C. L. Fitzwilliams: Syphilitic Affections of Bones met with in Childhood.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. J. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. H. French: Hypothyroidism.
TUESDAY.—4 P.M., Dr. E. Winter: Clinique (Medical). 5.15 P.M., Lecture:—Dr. W. C. Brown: Protozoon Dysentery at Home and Abroad.
WEDNESDAY.—4 P.M., Mr. C. Ryall: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. O. Grünbaum: Methods of Making an Accurate Prognosis in Renal Disease.
THURSDAY.—4 P.M., Dr. E. Cautley: Clinique (Medical). 5.15 P.M., Lecture:—Dr. F. Taylor: Pleuritic Effusion, its Diagnosis and Treatment.
FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Edwards: Urinary Surgery.
TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Yellow Fever.
WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M.. Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Mr. Ll. Williams: Oral Conditions in their Relations to General Conditions of Health or Disease.
THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture IV.)
FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: The More Serious Forms of Valvular Disease of the Heart.
SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.
TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. C. O. Hawthorne: The Meaning of Sphygmomanometric and Sphygmographic Records.
WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.
THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Dr. Rankin: Neurotic Dyspepsia.
FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.
SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie), 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. D. Gillies).
TUESDAY.—2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting). 4.30 P.M., Lecture:—Dr. G. F. Hadfield: Post-anæsthetic Vomiting.
WEDNESDAY.—Clinics:—2 P.M., Throat Operations (Mr. Gillies). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Mr. Stewart); 5.30 P.M., Eye Operations (Mr. Brooks).
THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappell). 4.30 P.M., Demonstration:—Selected Medical Cases (Dr. G. P. Chappel).
FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. Bosanquet: Tuberculosis in its Relation to Injuries and Accidents.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Encephalitis.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. F. Buzzard: Epilepsy.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY.—3.45 P.M., Lectures:—Mr. W. Stuart-Low: Methods of Examination.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Pathology of the Epidermis.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Tuberculosis of the Skin—I., Lupus Vulgaris; II., Tuberculosis Verrucosa Cutis; III., Scrofuloderma.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., A Demonstration of Clinical Cases will be given by Members of the Honorary Staff. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London, (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.), Royal National Orthopædic (9.30 A.M. and 4 P.M.).

WEDNESDAY (22nd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's 2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (23rd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal National Orthopædic (9 A.M. and 3.30 P.M.), Royal Ear (2 P.M.), Children Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Royal National Orthopædic (3.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.)., Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (25th).—Royal Free (9A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Two Lectures
ON
UNICELLULA CANCRI:
THE PARASITE OF CANCER.

Delivered before the Royal College of Surgeons of England

BY SIR HENRY BUTLIN, BART., F.R.C.S.,
PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; HUNTERIAN PROFESSOR.

LECTURE I.—THE PROTOZOA.

MR. PRESIDENT AND GENTLEMEN,—In the Bradshaw lecture of November, 1905, I put forward the proposition that "the carcinoma cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself; and that it lives as a parasite in the body of the animal which is affected with carcinoma, deriving its nourishment from this host, and doing nothing to repay the host for the sustenance of which it robs him."[1] Until shortly before I delivered the lecture I thought that I was the first person to suggest that the cancer cell is itself the parasite of cancer, but I found that Hauser had done so in 1903.[2] And a couple of years ago Dr. Powell White showed me that he had done so in the Erasmus Wilson lectures at the Royal College of Surgeons as long ago as 1902.[3] But I think that neither White nor Hauser had carried the matter to its logical conclusion, so far as to insist that the cancer cell is a new organism—a new creation of animal being—not a mere changed cell.*

INTRODUCTORY REMARKS.

So far as I know, then, I stood alone in the belief that the cell of carcinoma is a new creation of living beings, consisting of a single cell, and governed by natural laws just as clear and just as defined as those which govern single-cell organisms which are recognised by naturalists. In 1905 I maintained this view only for the cells of carcinoma. For the last five years and more the matter has been constantly before my mind. A great deal of new information and material has been provided during that period, and I am able now to maintain the view, not only for carcinoma, but for every variety of malignant disease.

I am quite aware that my ignorance of biology and of the lowest forms of animal life may render my attempt ridiculous in the eyes of naturalists. And I should never have ventured to undertake the task had there been any person particularly fitted for it, and willing to accept it. A wide grasp of three kinds of knowledge is required—a knowledge of the protozoa, experience of experimental investigation of cancer, and experience of the clinical pathology of cancer in the human subject. I do not know any one person who combines these three kinds of knowledge in himself.

There is only one distinguished protozoologist, so far as I know, who is engaged in the investigation of cancer—Professor Calkins, of the Columbia University, of New York—and he is not a medical man. And it is, I am sorry to say, notorious that the masters of experimental investigation are, for the most part, very ignorant of the clinical pathology of cancer, while it is equally true that the physicians and surgeons who have studied cancer from the clinical and microscopical aspects are not acquainted with protozoology or with experimental investigation.

The class to which I have the honour to belong—the clinical pathologists—is looked down upon by the other two classes, and I have been told that its day is past. But I claim a right to present my theory on the ground that I have spent a great deal of time in the course of many years in the study of the clinical pathology of cancer, and that I have been closely observant of the actual work of the Imperial Cancer Research since its foundation, have constantly associated with the staff, and have been a member of the Publication Committee of all the scientific reports which have been published by the Research On the other hand, I am wholly dependent for my statements on the life-history of the protozoa on the works of Calkins and Doflein, and the references which I have found in them, and to some pretty sharp criticism of my views in a letter which Professor Calkins was kind enough to write me.

I shall divide the subject into two parts. In the first part I shall endeavour to show that there is no essential difference between cancer cells and certain other parasites in the relation to their host. In the second part I shall show that almost all the phenomena of cancer with which I am acquainted can be readily explained on this theory. The parasites of which I am going to speak are the protozoa; I am not going to speak of such micro-organisms as bacilli and bacteria. I use the protozoa not because I intend to insist that the cancer cells must be included amongst the protozoa, but because they most closely resemble the protozoa in their relation to the body of the host, and perhaps in their mutual relations.

SOME CHARACTERISTICS OF PARASITIC PROTOZOA.

Certain of the protozoa appear only to live as parasites, whilst others of them are never parasitic, and others, again, are able to exist either as parasites or external to the body of any host. The powers of the parasites are strangely and strictly defined. Doflein[4] (of whose work I am going to make very free use) says:—

> When a protozoon gets into another organism there begins at once a fight between the two, which ends in an easy victory of the larger, many-celled beast if the protozoon is not a parasite, and if the many-celled beast enjoys its normal natural resistance. But if the protozoon is fitted for parasitism then the fight is in earnest. And in this fight that organism conquers which is able to overcome the other with its fighting weapons.[5]

But it is quite certain that every parasitic protozoon which finds its suitable host does not succeed in holding its own against the resistance of the host.

Many groups of parasites are limited to certain groups of hosts—the Sarcosporidiidæ, for instance, to air-breathing vertebrates—whilst the Gregarinidæ have not been found in vertebrate hosts.[6] But the limitations are much more strict than this. For, of the same species of parasite, different varieties are found in different varieties of a species of host. Thus, the Sarcosporidiidæ, which are believed to be exclusively found in mammals,[7] and which have been found in horses, cows, buffaloes, mice, rats, man, &c., do not all occur equally and at random in all these animals, but certain varieties of the Sarcosporidiidæ occur only in certain varieties of mammal. *Sarcocystis miescheriana* inhabits the body of the pig; *Sarcocystis tenella* loves the sheep; while *Sarcocystis muris* is a parasite of the house-mouse and the rat. And those varieties of parasite which are particular to certain varieties of mammal, as the *Babesia bigemina* is to cattle, cannot be implanted in other mammals. Experiments which have been made on rats, guinea-pigs, sheep, and pigeons have always failed.[8] On the other hand, there are parasites which can exist in several or many varieties of host, yet even these exhibit strange powers of selection. Thus, *Trypanosoma brucei* and *Trypanosoma lewisi* can breed in dogs, in the blood of the same animal, but if they are injected from this blood into rats, *Trypanosoma brucei* disappears, and only *Trypanosoma lewisi* lives and thrives.[9]

Just as particular varieties of protozoa are limited to particular varieties of host, so they are often limited in like manner to particular parts of the bodies of their hosts. Thus, the Sarcosporidiidæ are parasites of muscles; Trypanosoma is a blood parasite; the Coccidiidæ are parasites of cells, particularly of epithelial cells.[10] But they exhibit powers of selection much more marked than this. *Myxobolus cyprini* is a parasite of the kidney epithelium of the carp. The Sarcosporidiidæ not only affect the muscles, but most of the varieties affect particular muscles or groups of muscles. Thus, *Sarcocystis miescheriana* takes to the muscles of the larynx, to the diaphragm, and intercostal muscles; *Sarcocystis muris* affects the muscles of the trunk. And although several varieties of Sarcosporidiidæ are chiefly found in the muscles in the neighbourhood of the alimentary canal, which they may have easily reached from the mouth or œsophagus, others of them are found in muscles far distant from the alimentary canal, such as the intercostal muscles or the muscles of the trunk. Other parasites appear to be equally at home in several or many tissues of the host. *Nosema bombycis* (which produces the pébrine disease of the silkworm) occurs in the intestine, the fat bodies, the sexual organs—in short, in all the organs of the *Bombyx mori*.

* "All the phenomena of malignant and other tumours can be explained on other grounds—viz., on the view that the cells take on an independent mode of growth, and behave as parasites themselves." "Once the cells have acquired this habit (Adami's Habit of Growth) they behave as independent parasites." (White, loc. cit.)

And, far more remarkable and interesting than this, is the generalisation which may take place of parasites which are usually limited to a single structure of the host. Thus, *Myxobolus pfeifferi*, which is usually a harmless parasite in the kidney of the barbel, makes terrible havoc of the same fish in the water of certain rivers (the Seine, the Marne, the Maas, the Rhine, and Mosel), where it attacks almost all the organs of the body of the fish—the connective tissue of the intestine, the kidney, the spleen, the liver, but, above all, the muscular system, in which it forms great lumps and tumours, which stand out on the surface of the animal, and are quite characteristic of the barbel-sickness (*Barbenseuche*)[11] (Figs. 1 and 2).

Migration of Parasitic Protozoa.

It is possible that the protozoa, which are parasitic (some of them, at least), take an active part in their migration. But they are also carried in the blood and lymph to the organs and tissues in which they are generalised. Thus, *Isospora lieberkühni* (a parasite of the frog) first attacks the epithelium of the intestine, then penetrates into the vessels of the mucous membrane, and is carried by the blood to the lungs, liver, spleen, and other parts. *Entamœba histolyca*, the parasite of dysentery, makes its way through the walls of the rectum, and is supposed to be conveyed through the ductus choledochus into the liver. *Lymphosporidium calkins* (which produces severe epidemics in fish) appears in the form of small amœboid bodies in the lymph, attacks the muscles of the intestines and other organs, passes again into the lymph in its developed form, and produces numerous spores, which are conveyed to all parts of the body. It is interesting to observe the changes which take place in many of the protozoa, either to adapt them to parasitism or to altered conditions of life in the bodies of different hosts. Thus the Trypanosoma will vary in size, in the situation of its nucleus, &c., according to the medium in which it lives. *Trypanosoma lewisi* loses its undulating membrane in certain artificial cultures, and the Sarcosporidiidæ are not constant in form, for the cells, closely packed together during their development, mutually deform one another.[12]

Of liability of animals of the same species to a particular parasite, the evidence goes to prove that some individuals of a species are immune to the attack of a parasite, other individuals recover from the attack of a parasite, while other individuals again suffer badly from it or die. Take, as an example, the hæmoglobinuria of cattle (Texas fever), which is attributed to *Babesia bigemina*, a parasite which is not directly transferred from cow to cow, but is introduced into the cattle by a beetle (*Boophilus annulatus*).[13] Whole herds are attacked in the plains of Texas. But all the animals do not show symptoms of the disease, and some of those which are attacked recover. Pigniéres gives an account of a herd of 1000 adult cattle and 450 calves. Of the adults 630 died—an enormous mortality—but only 10 of the 450 calves perished of the disease. Calves, if they suffer at all, suffer mildly. There is generally no hæmoglobinuria, and at the end of a fortnight they are often quite recovered. Nevertheless, the *Babesia* may still be found in the blood of these recovered calves, so that they appear to have acquired immunity against the poison of the parasite. Whether they can be artificially immunised by the injection of the blood of beasts which have been cured of the disease has not yet been clearly ascertained.

Liability of Parasitic Protozoa to Death.

Although some of the parasites are able to take formed nourishment, most of them, and all the cell parasites, live by osmosis.[14] The Sporozoa, for instance, live exclusively by the osmotic taking of fluid nourishment.[15] Many of them perish with their host, for even if they escape from the dead body of the host, they may be unable to exist outside the body of a host. But they often exhibit a marked tenacity of life; for they may live for days after the death of the host, and of every tisue and cell of the host.

With regard to the liability of parasitic protozoa to death, it is held by Weismann and his school that the protozoa are immortal, in the sense that the young animals are in part composed of the substance of the parent. As a matter of fact, they undergo degeneration, are liable to disease, fade, waste, and die, like other living creatures; and they are often killed by the invasion of their bodies by micro-organisms—the bacteria—which are then parasites of parasites. I must ask you to bear this in mind when we come to consider the cells of cancer presently.[16] It appears probable that the body of the host contains, or may produce on demand, a substance dangerous to the life of the parasite which is in it. Of this the parasite may die. But if it can withstand the dangerous substance it seems to gain greater strength. It has acquired immunity by its successful resistance to the dangerous substance, and may flourish more actively than before. But the activity of a parasite is probably not always the same. For, as they show alternate periods of activity and depression in cultures, eating more, growing faster, multiplying abundantly at one time, and displaying sluggard qualities at another (Actinosphæria, Infusoria, &c.), so it is probable they are subject to similar periods of activity and depression in the body of the host.[17] Whether, during these periods of depression they are devoured alive by phagocytes I do not know, but their dead bodies appear to be eaten by phagocytes.[18]

Effects of the Parasites on their Hosts.

The effect of parasites on their hosts depends largely on whether they produce toxins dangerous to the host or not. Many of them (such as the parasite of malaria) are toxic. And these are naturally much more dangerous to the host than the non-toxic parasites. But their virulence varies, like their vital activity; they are seldom or never so actively virulent as the bacteria and bacilli, and take much longer to produce serious or fatal illness in the host. The non-toxic parasites are much less dangerous to life. They are often unperceived—are mere "commensales." But they may destroy the cells and tissues which they attack to such an extent as to produce serious effects upon the health of the host. They may destroy the host by enormous increase in numbers, and particularly by interfering with the working of vital organs. I have already mentioned the barbel-sickness, which is so fatal to the fish in France and Germany. The tumours sometimes ulcerate. The Coccidiidæ appear to produce their effects by destruction of the tissues they invade. *Eimeria stiedæ*—a common coccidium of the rabbit—causes the formation of tumours which may grow as large as a hazel-nut, and contain fluid, in which are found quantities of epithelial cells and coccidia.[19] *Lymphosporidium calkins* (a parasite of fish to which I have already referred) is apt to fill the lymph vessels so full that serious disturbance, the formation of ulcers, and death result from the stoppage of the flow of lymph.[20] *Sarcocystis tenella* sometimes chokes sheep by producing great sarcosporidian tumours in the neighbourhood of the air passages.[21]

It seems probable that some parasites are capable of existing during long periods of time, even when they are not living their usual life, in the sense that a parasite which is, under ordinary circumstances, toxic to the host, may cease to be toxic, yet still exist. Thus, *Babesia bigemina* is often found in the blood of calves which have long recovered from the disease which it produces. It is well known that human beings who have contracted malaria may recover from it and may live for years without an attack, and then may be suddenly and unexpectedly attacked, even when they have been living meanwhile in non-malarial regions. It is evident the parasite is living in the body of the host during this long period, but it is almost equally evident that it just maintains its existence, and has lost its activity in the face of the increased resistance of the host.

Explanation of Power of Selection.

It will be noticed that I have used the term "power of selection" in speaking of the predilection of particular parasites for particular species of animals, for particular varieties of those species, and for particular organs and tissues of their hosts. The only reasonable explanation of these predilections is that the parasite finds the nourishment suitable to it in the particular host and parts of the host which it infests, or encounters less resistance there. *Eimeria stiedæ*, for instance, which is contained in the grass on which many animals are feeding, must have an opportunity of entering the alimentary canal of cows, of horses, of sheep, and other animals. And undoubtedly it does enter it. But the only one of the animals which feed on the grass in which they are so abundant which harbours and nourishes the parasite is the rabbit. The waters which contain *Myxobolus pfeifferi* also contain *Myxobolus cyprini* and *Myxobolus neurobius*, and all kinds of fish which inhabit these waters must swallow myriads of all three varieties of parasite. But only the one particular parasite thrives in the one particular

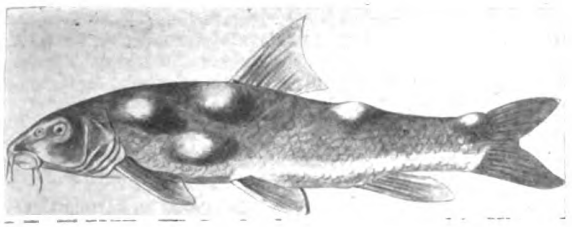

FIG. 1.—Barbel suffering from *Barbenseuche*; tumours formed by *Myzobolus pfeifferi* (after Doflein). *Protozoenkunde*. II. Aufl., Jena, 1909, Fig. 730.

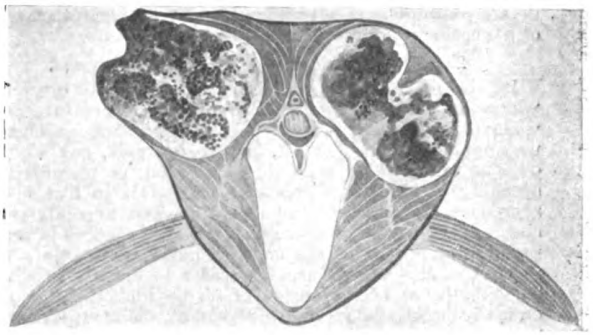

FIG. 2.—Section of a barbel, showing symmetrical tumours, that on the right side ulcerated (Doflein, Fig. 731).

FIG. 3.—Squamous carcinoma of tongue, the cells of which are elongated like spindle-cells.

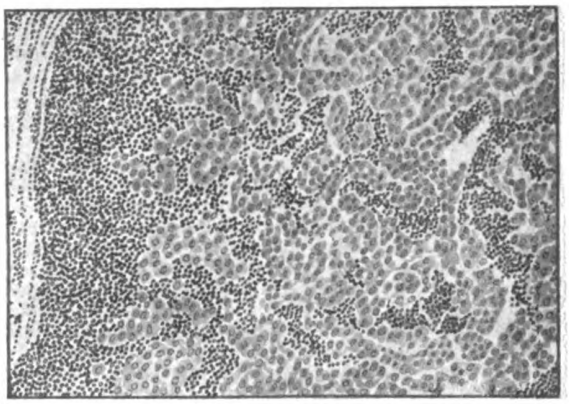

FIG. 4.—Axillary glands removed 20 years after successful removal of the breast.*

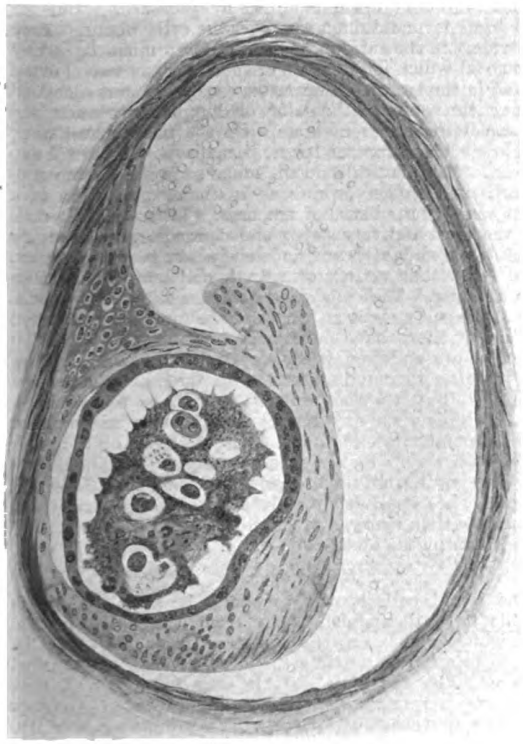

FIG. 5.—Degenerated cancer cells in an organised thrombus in a blood-vessel (after Martin B. Schmidt). Die Verbreitungswege der Karzinome, Jena, 1903. Plate, Fig. 3.

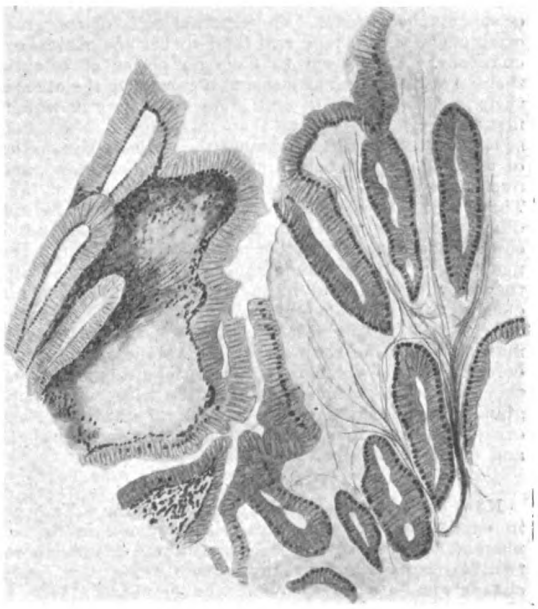

FIG. 6.—Columnar-celled cancer of the rectum (after Cripps). Diseases of the Rectum and Anus, 1884, Pl. VI.

* The history of this case is very interesting. In 1895 Sir James Paget sent me a lady whose left breast he had amputated for carcinoma about 1875. The glands had not been removed. About 1885 Mr. Stephen Paget destroyed with the cautery "some carcinomatous tubercles in the right breast." When I saw her in 1895 there was no recurrence in either breast, but a mass of glands in the left axilla, which were easily removed. She came to see me in 1898. There was no recurrence either in the breast or in the axilla on the left side, but there was recurrence in the right breast, for which I amputated the breast (XI., 201).

variety of fish which it affects. I would keep constantly before your minds this explanation of the power of selection of parasitic protozoa.

Two Characters Common to Parasitic Protozoa.

Before leaving the parasitic protozoa, two characters which they have in common should be referred to. First, whatever office the parasite may serve, whatever effect it may produce on the host, it, for its own part, has only two objects in view, if such an expression is permitted in speaking of so lowly a creature. It strives to live and to reproduce—to maintain the individual and to continue the species. If, in a suitable host, it does not succeed in reaching a suitable part of the body within a reasonable period it will die, and the species will cease to exist in that host. The rapidity and completeness of its destruction will depend on many circumstances, but the general statement is correct. Second, it breeds true. The young animals are always of the same species as the animals from which they were derived. I believe some doubt has been expressed whether Hæmosporidiidæ may not be derived from Flagellidia.[22] I am not competent to speak on this, but it may be stated quite certainly that Sporozoa are not bred from Rhizopoda or Rhizopoda from Ciliata—that *Sarcocystis miescheriana* does not become *Sarcocystis muris*, and that *Nosema bombycis* never produce *Nosema destruens* or the reverse.†

I now come to the

COMPARISON BETWEEN THE CANCER CELL AND THE PARASITIC PROTOZOA

in their life-history and their relation to the host. And I propose to treat it in the reverse order, taking the individual cells first, and dealing with the characters which they have in common afterwards. First, I must premise that there is no one cell for every kind of malignant disease, nor is there one cell for the carcinomata and another cell for the sarcomata. Every variety of malignant tumour has its own typical cell, and the characters, the selection of locality, and relations of each variety of cancer cell to the host are sharply defined, and differ as widely as, though not more widely than, those of the varieties of protozoa which belong to the same species.

Characters of Cancer Cells.

Take first the cells which resemble the cells of the deeper layers of the epidermis or of the appendages of the skin. They are very regular in size and shape, and are collected in masses in spaces of the connective tissue, usually of the skin or subcutaneous tissue. The external cells of the group are often modified in shape and tend to become cubical or even columnar. They seem to have no power of establishing themselves in distant tissues and organs. On the other hand, their tenacity of life in and around the part in which they first appeared is little less than marvellous. Next, take the squamous cells. They resemble the cells of the epithelium of the skin, but are not so regular in size and shape, and the nuclei are large—out of proportion to the size of the cell. They form masses which sometimes recall the natural dipping of the epithelium between the papillæ, but often seem to be massed together with no further design than to find sitting, or even standing, room. And in this attempt they are often squeezed in such a manner that they may be elongated and look more like spindle cells than squamous cells (Fig. 3). They extend into the spaces between the muscular fibres as they grow beneath the surface, forming columns of cells which are easily distinguishable. Whenever they are in close and easy relation with the lymphatic glands, it may be accepted as a rule to which there are few exceptions, that they will find their way into those glands, and will grow and multiply there.

Cells of Spheroidal Type.

Now, consider the cells of spheroidal type. They collect in spaces of the connective tissue, sometimes in such a manner as to recall the structure of the gland whose epithelium they pattern. They spread along the lymphatic channels and are conveyed into the lymphatic glands, where they are well received and flourish. They are conveyed by the blood into other organs. They can live and multiply in many organs; but they select, by preference, the liver and lungs, and the medullary tissue of the bones, particularly of the femur and vertebræ of the lumbar region, just as certain sarcosporidiidæ have a liking not merely for muscles, but for certain muscles or groups of muscles. They exhibit a wonderful tenacity of life, for, after lying dormant for many years (as many as nine or ten or more), they may suddenly thrive and multiply and produce large masses of their like in the space of a few weeks or months (Fig. 4). Although they are probably chiefly conveyed to different regions of the body in the form of single young cells, it is also well known that masses of them grow into the interior of blood and lymphatic vessels,[23] and that emboli of them may be carried into parts which are favourable to their reception. It is also known that many of them perish in their journeying. They may be found in blood-vessels and in the thoracic duct in a condition of degeneration and decay (Fig. 5).

Columnar or Cylindrical Cell.

One of the most interesting and favourable objects of study is the columnar or cylindrical cell. It resembles the cells of the columnar glands of the alimentary tract (Fig. 6). Its tendency is to arrange itself in the same fashion as the columnar cells are arranged in the glands of the stomach and intestine, sometimes so precisely that it is difficult to believe that the section of the carcinoma is not a section of normal glands. But the imitation is usually much coarser, and there is evidence of slovenly work in the characters and disposition of the cells. As in the previous case, the cell makes its way into the surrounding and subjacent tissues, into the lymphatics and lymphatic glands, and is there speedily at home. It also has a great fancy for the liver, and, in a less degree, for the lung, and it now and then grows in the medullary tissue of one of the long bones—the humerus, for example—or such a flat bone as the ilium.

Spindle Cells.

Now consider the group of spindle cells. They are elongated, tapering at each end. They vary much in size, and their form is often modified by pressure. But the general form is maintained wherever the cells occur. They spread widely in the surrounding tissues. It must be a very wide removal which is to get rid of them. They travel in the blood and in the lymph, so far as we can judge, but although they may thrive in the interior of lymphatic glands, the glands are often free from them. On the other hand, they have a great liking for the lungs, perhaps more than for any other part. They multiply in the lungs so rapidly as to produce large and numerous masses in them, and that is a frequent cause of the death of the host. These spindle cells are for the most part very strong and vigorous, grow quickly and multiply abundantly, and find subsistence in many organs.

There is another variety of spindle cell which multiplies to form tumours. The cells are often of small size, and the outline of the cell may be so faint and the nucleus so distinct that some of them have been called "fibro-nucleated."[24] These cells are endowed with very limited powers. They spread into the surrounding parts; in these parts they live and thrive. But they appear quite unable to effect a successful attack upon any distant part, for they are not met with in the neighbouring glands, or in the liver, or lungs, or bones, or elsewhere. It is no excuse to say that their form and size are not favourable to transference by the blood and lymph. They are small and of convenient shape for transfers, much more so than many large spindle cells which are readily conveyed both by the blood and lymph.

Round Cells.

Of the round cells it may generally be said that it is very difficult to distinguish them from the cells of the masses which make up the infective tumours (Fig. 7). Indeed, it is often impossible to do so by their anatomical characters. For the most part it may be affirmed that they possess a remarkable vitality, not exceeded (seldom equalled) by any other cancer cell. They multiply rapidly, so rapidly that in some cases they produce immense masses in a few weeks, and the growth of the mass may be associated with symptoms of general fever. They seem much less influenced by the resistance of the host, or much more capable of finding nourishment, or less dependent on a very special diet, than most other cancer cells. For they seem very little limited to particular organs and tissues compared with most other varieties of cell. They flourish in

† There are other properties on which I must not touch, such as the periodicity which some of the protozoa exhibit in relation to their vitality. Time will not permit me to do so. (Calkins, Protozoology, 1909, p. 106.)

the lymphatic glands, if they reach them, in the bones, skin, and subcutaneous tissue, kidneys, liver, lungs—indeed, like *Nosema bombycis*, almost everywhere. I believe they would spread all over the body if the host were not destroyed by them before they have had the opportunity to do so.

Giant Cells.

There is one variety of cell which I must not pass over without notice—the giant cell. These cells only form a certain proportion of the masses in which they occur—less than one-half—and the remainder of the mass is composed usually of spindle cells. Having regard to their size alone it is not surprising that giant cells travel with difficulty in the blood and lymph. It would be expected that the spindle cells of which the mass is chiefly formed might travel and establish themselves in other places. But it is notorious that they seldom do so.

Resemblances of Cancer Cells to Parasitic Protozoa.

These examples will suffice to illustrate some of the resemblances of the life-history of the cancer cell to that of the parasitic protozoa. It will be seen that they are as careful in the selection of locality as are the varieties of parasitic protozoa. They spread in the interstices of the tissues in which they first appear, as do certain of the protozoa. They are conveyed in the blood and lymph, as the parasitic protozoa are. They are deposited in distant tissues and organs, like the parasitic protozoa, and they show just the same predilection for certain tissues and organs as do the protozoa. They are like many of the parasitic protozoa in the fact that they live almost entirely by osmosis. Like the protozoa, they sometimes live for long periods of time in the body of the host without any sign of their presence, and perhaps in a state of lethargy, until their vigour and activity are restored to them by some lowering of the resistance of the host, or by some change in the part in which they had been lying, which renders it more suitable to their necessities. They do not appear to furnish toxins which are dangerous to the health of the host, so that their effects are produced (like the effects of such parasites as *Myxobolus pfeifferi*) by mechanical causes—destruction of the tissues in which they live and multiply, the stoppage of blood and lymphatic vessels, and

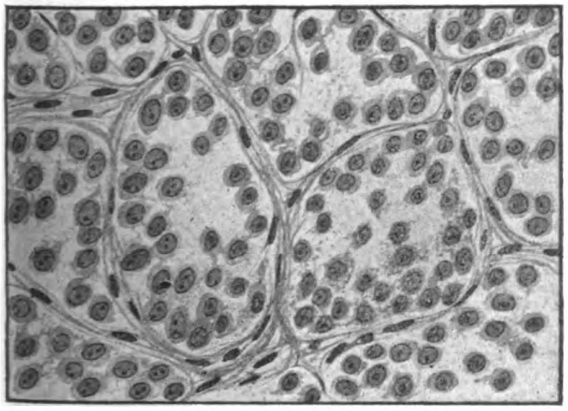

FIG. 7.—Large round-celled sarcoma of testis.

the changes consequent on this stoppage. These conditions are naturally more dangerous when they affect the vital parts. On the other hand, when like the protozoa the cancer cells are attacked by pathogenic organisms, bacteria and bacilli (as is almost invariably the case when they become exposed), they are rapidly destroyed, sometimes in great masses, and the effect upon the host is disastrous.

Some cancer cells can live for a long time outside the body of the host, although they do not, so far as we know, belong to the class of organisms which are sometimes parasitic, sometimes not parasitic. I am not aware of any investigations to discover the longest period during which cancer cells can exist outside the body of the host. We want further information on this point. But it is certain that they can live for weeks in glass tubes and then be implanted, as if they were just taken from the mass in which they lived. At present the cancer cells can only be implanted with success in animals of the same species as the animal from which they were taken. In this respect, again, they resemble certain of the protozoa. It may be that, with greater practice and experience, they will be induced to grow and multiply in animals of a different species, but I very much doubt it, just as I doubt whether *Babesia bigemina*—a parasite of cattle—will be successfully implanted in a sheep. Cancer cells, like the parasitic protozoa, are never transformed into tissues of the host, and the structures which they cause to be built up are for their own service, not for the service of the host. They are not themselves transformed into any other kind of tissue, nor do they transform the cells of the body into cancer cells. From the moment they are first unmistakably cancer cells, they remain cancer cells, and from that moment they pursue only those two objects which are pursued by the protozoa—to live and to reproduce. And if they fail in these objects both the individual and the species perish. Of this ample evidence has been furnished in these last years, particularly by the Imperial Cancer Research for animals, and by Sir Alfred Pearce Gould for man.[25] In reproduction they breed as true as any protozoon. Not only do carcinoma cells reproduce carcinoma cells and not sarcoma cells, but it is invariably the same variety of cell which is reproduced, with the same properties and powers and characteristics. It has been said that the cancer cells differ from the protozoa in the circumstance that they are not constant in their method of reproduction, that they multiply by budding or by mitosis, as pleases them, and that the protozoa never do so. If all the protozoa were thrown into a common receptacle for study they would also be found to vary in their method of reproduction. I believe it is only because the cancer cells have been treated in this fashion that they seem to be subject to no method. But separate them and study them in families, and I think it will be found that they are just as bound in this respect as the families of protozoa. I suspect that the old rule which was laid down (I do not remember by whom or exactly when) is as correct now as it was—that the cells of carcinoma multiply by endogenous multiplication, and that the cells of sarcoma multiply by fission or by budding. The terms used may be different, but I suspect the facts will be the same.

Physiological Characters of the Cancer Cell.

I will not describe the physiological characters of the cancer cell in my own terms, for fear it should be thought that I exaggerate. I will quote Professor Calkins[26]:—

> Functionally the carcinoma cell is a more perfect type than its orderly colleagues of the epithelium. It takes in and assimilates abundance of food, grows rapidly (especially when near the immediate source of food—that is, at the growing edge), and reproduces its kind through the same complicated processes that characterise free living cells. In short, it is a complete animal organism in itself, simulating in many ways the parasitic protozoon, but differing in some of the most important respects connected with the continued life of the latter.

I understand that the important respects in which the cancer cell differs from the parasitic protozoa are:—

> 1. "That the cancer cell, so far as we know, undergoes no processes analogous to fertilisation."[27] 2. "That it cannot live apart from the organism in which it grows; it cannot be cultivated on artificial media, as we cultivate amœbæ and flagellates."[28]

To the second of these objections it is already claimed by two workers in the Rockefeller Institute that they have cultivated cancer cells in artificial media. To the first, one can only say that if in the future no process analogous to fertilisation is discovered in the life-history of the cancer cells, it is evident that the import of the process of fertilisation will have to be reconsidered. If the cancer cell does not conform in all respects to the laws which are believed to govern the protozoa, it will still remain "a complete animal organism in itself." A new phylum will have to be founded for it, and laws drawn up appropriate to its life.

An Introductory Address

ON

THE MEDICAL ASPECTS OF SOME SOCIAL QUESTIONS.

Delivered before the Forfarshire Medical Association on Oct. 13th, 1911,

BY G. A. GIBSON, M.D., LL.D.,

PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

GENTLEMEN,—It is possible—nay, even probable—that on such an occasion as this our thoughts are apt to be reminiscent of the past, rather than expectant of the future. It is my intention to-day to seize the opportunity which your kindness affords me in order to ask you to look forwards, rather than backwards.

INTRODUCTORY REMARKS.

The present is so full of social projects—some of them of a truly adventurous kind—that it is well for—nay, incumbent upon—us to consider whither we are going. Closely connected with such thoughts is the question whether the world, as a whole, is improving. In spite of the material progress and luxurious habits of our age, we often feel it necessary to ask ourselves if the accumulated wealth which has been heaped up in this country during the past century is to be taken as evidence of greater health of our nation. We must endeavour to ascertain whether our success in amassing riches has brought any real improvement in the condition of the people. It seems in my humble judgment that such subjects are at least open to debate, and it has been borne in upon me (who cannot in any way be regarded as *laudator temporis acti*) that, in some respects, we are really in no better condition than we were before.

Our great aim, as belonging to the medical profession, is to do what we can for the good of all. We are all members of one body politic, and, whether we believe in the principles of Individualism or of Socialism, we desire the welfare of the people at large—*salus populi suprema lex.*

In the remarks about to be made, let me make it quite clear that they are addressed by a working man to other working men. We are in the habit of speaking of those who labour with might and main as "working like blacks." Assuredly the medical man who desires to fit himself for the performance of his duties, and who is reasonably successful in his aims, may justly be regarded as working like ten blacks.

It will be difficult in this address altogether to steer clear of politics; but even if a political bias should show itself, there will certainly be a total absence of any attempt to impute unworthy motives, or to impugn the personal sincerity of any of the politicians from whom we cannot fail, as men of science, to differ.

It must also be premised that in entering upon any consideration of the subject which is to occupy us we must, above everything, avoid all that savours of flippancy. Professing, as we do, the healing art, which leads us to spend our lives, as it were, "in sight of the very Gate of Eternity"—as my dear old friend, Sir William Gairdner, expressed it in one of his most beautiful addresses—we shall always approach such matters in the reverent spirit of men engaged in a holy calling. Righteous indignation or noble rage we may well feel at the sight of wrongs, or the sound of lies, and when stirred in this way we would be false to our better selves if we held our peace; this is quite other than the satirical cynicism of the light-minded.

The advance of democracy is steadily increasing the influence of the working man, and signs are not wanting that he will use his power. We may well believe that he will employ it, on the whole, wisely. It is evident that he will not much longer support the longshore loafer, the sturdy beggar, and the professionally unemployed; it is likewise clear that he is tired of witnessing the sentimental pauperising of the picturesque (and often criminal) alien, as well as the reprehensible toleration of all types of our own home-grown Weary Willies. How to prevent the increase of the unemployable is a matter which many intelligent artisans have discussed with me.

We need not, in my opinion, fear the swelling waves of democratic thinkers in our country. Judging by the past, the modes of social and political thought in the future, with some temporary aberrations from time to time, will return to sane channels. The strongest discipline that this country ever had was that under the Commonwealth. Many of us feel that it were well for our country to enjoy—if such a phrase may be employed—something of the kind again. It is our bounden duty to use such influence as we have with our other working brethren to help them to use their power in the right direction. There is a general rule, to which few exceptions can be found from the study of history, that no nation can retrace its steps. It therefore behoves us to use our best endeavours to see that the direction in which we are tending is along the lines of safety.

Before taking up the topics upon which you will allow me more particularly to dwell, it seems necessary to make a few preliminary remarks regarding a subject which has been and will be much in our minds.

NATIONAL INSURANCE BILL.

Criticism of the National Insurance Bill is rendered somewhat difficult by a sincere sympathy with most of its declared aims. Many of us on the introduction of the Bill welcomed it as an attempt to lead a large proportion of our population to make provision against the accidents of life; this has notoriously been left undone in the past. We would have wished to have gone further in some directions, particularly in making provision for the widows and children of deceased workmen. We rejoiced, nevertheless, to think that a serious attempt was at last being made to introduce a contributory scheme of national insurance, in which those in whose interest it was introduced should be taught the benefit of self-help.

But most of us have been led to view the Bill with suspicion, on account of its preposterous sections in respect of medical benefits. The amazing proposal that attendance should be rendered by the medical profession on terms, under the circumstances, almost gratuitous, to voluntary insurers of unlimited wealth, was in itself enough to make any reasonable being suspicious of the sanity of its author. Under the unanimous pressure of common-sense, this attempt to foist the well-to-do on us as recipients of charity has already faded away like the snow on a dyke in the morning sun.

The *income limit* of those now suggested as entitled to medical benefits is still a vexed question. The original proposal, after the elimination of the voluntary clauses, dealt severely, as usual, with the unfortunate payer of income-tax. The clauses proposing to enact that all those who do not pay income-tax should enjoy medical benefits was, we have been told, due to the fact that the wit of man was unequal to the effort of devising any other basis. What a humiliating confession of political incapacity and legislative ineptitude! In the storm and stress of medical criticism, the suggested solution is to leave the determination of the question to the local authorities. Does such a suggestion bear any mark of real statesmanship? It is only a compromise, and a feeble compromise; it would undoubtedly have been far wiser from the first to have suggested a scheme of graduated payments for medical assistance.

Little need be said about *freedom in the choice* of a doctor. Such freedom was demanded by everyone. We have not yet reached a belief in equality of intellect. The Hibernian Socialist of the ancient chestnut put the matter in a nutshell when, to his leading statement: "One man is as good as another," he added, in a burst of confidence, "and sometimes, indeed, even better."

Few words are required in regard to the absolute necessity of *adequate medical control.* Sufficient medical representation upon all committees is, and must be, the basis for all efficient medical service. This, also, has been conceded as the result of powerful medical representations.[1]

[1] The hopes expressed when this address was delivered with regard to the amendments to the National Insurance Bill have been almost entirely disappointed. Of all the points in respect of which the medical profession insisted on modification only one has been yielded—that allowing free choice of the doctor; it was so obvious that the nation would tolerate nothing else that we have no reason for any particular gratitude on this head. As the Bill in its present condition is an outrageous violation of the justice we have every reason to expect at the hands of the State, there is nothing left for us but to decline, in the most absolute way, to take part in carrying out any of its provisions. There can be no doubt that in Scotland we shall be able to stand fast in passive resistance to intolerable tyranny.—G. A. G.

Most of the points which have been referred to may be, let us hope, regarded as mainly of historic interest. It will not do, however, to slacken our vigilance, as in Committee, or on its third reading, some of the discredited clauses may, perchance, find their way back again, and until the Bill has been thoroughly mended or completely ended we must be on our guard.

To us there is one gratifying feature. The discussions which have been held have not only taught us our power but shown our solidarity. Many of us here have engaged in agitation, forced upon us by the dangers to which numerous colleagues have been exposed. It has indeed been a matter of heartfelt gladness that we have stood, and shall stand, shoulder to shoulder in the crisis of our profession.

General Criticism of the Bill.

In thinking over schemes for the good of the people one of the humorous yet touching scenes in the twenty-second chapter of the third book of Sterne's masterpiece will probably present itself to many of you:—

Pray what's the matter? Who is there? cried my father, waking, the moment the door began to creak.—I wish the smith would give a peep at that confounded hinge.—'Tis nothing an' please your honour, said Trim, but two mortars I am bringing in.—They shan't make a clatter with them here, cried my father hastily.—If Dr. Slop has any drugs to pound, let him do it in the kitchen.—May it please your honour, cried Trim, they are two mortar-pieces for a siege next summer, which I have been making out of a pair of jack-boots, which Obadiah told me your honour had left off wearing.—By Heaven! cried my father, springing out of his chair, as he swore—I have not one appointment belonging to me, which I set so much store by as I do by these jack-boots—they were our great grandfather's, brother Toby—they were hereditary. Then I fear, quoth my uncle Toby, Trim has cut off the entail.—I have only cut off the tops, an' please your honour, cried Trim.—I hate perpetuities as much as any man alive, cried my father—but these jack-boots, continued he (smiling, though very angry at the same time) have been in the family, brother, ever since the civil wars:—Sir Roger Shandy wore them at the battle of Marston-Moor.—I declare I would not have taken ten pounds for them.—I'll pay you the money, brother Shandy, quoth my uncle Toby, looking at the two mortars with infinite pleasure, and putting his hand into his breeches pocket as he viewed them—I'll pay you the ten pounds this moment with all my heart and soul.—

Brother Toby, replied my father, altering his tone, you care not what money you dissipate and throw away, provided, continued he, 'tis but upon a siege.—Have I not one hundred and twenty pounds a year, besides my half pay? cried my uncle Toby.—What is that—replied my father hastily—to ten pounds for a pair of jack-boots?—twelve guineas for your pontoons?—half as much for your Dutch draw-bridge?—to say nothing of the train of little brass artillery you bespoke last week, with twenty other preparations for the siege of Messina: believe me, dear brother Toby, continued my father, taking him kindly by the hand—these military operations of yours are above your strength;—you mean well, brother—but they carry you into greater expenses than you were first aware of;—and take my word, dear Toby, they will in the end quite ruin your fortune, and make a beggar of you.—What signifies it if they do, brother, replied my uncle Toby, so long as we know 'tis for the good of the nation?—

My father could not help smiling for his soul—his anger at the worst was never more than a spark:—and the zeal and simplicity of Trim—and the generous (though hobby-horsical) gallantry of my uncle Toby, brought him into perfect good humour with them in an instant.

Generous Souls!—God prosper you both, and your mortar-pieces too! quoth my father to himself.

Here we have the whole gist of the matter—so long as we know it is for the good of the nation. It must be owned that it would be a hard task to find any resemblance between the demagogue orator and one of the most delightful characters of English classical fiction. There is, however, one aspect which the rampant politician and the genial soldier have in common. As the military operations of the latter were above his strength, so are the financial adventures of the former beyond his ability.

In a recent communication the author of the Bill has made a statement which throws a painful light upon the reason for its introduction. He tells us that its object is not to teach the people how to help themselves in any noble efforts, but simply to help themselves out of other people's pockets. In case there should be any suspicion of a parody let me give his exact words:—

The Insurance Bill provides that for every 4*d.* paid by the workman he shall receive benefits worth 9*d.* To aid the workers' contribution a sum of £17,000,000 per year is to be subscribed by the employers and tax-payers.

It is difficult to find phraseology adequate to meet such an admission as this.

But this doctrine of plunder is in itself based upon falsehood. The statement that for every 4*d.* paid by the workman he is to receive benefits of the value of 9*d.* is absolutely and grotesquely untrue. Every penny will in the long run be paid by himself. The specious inducement offered to the electors to vote for candidates of the same political complexion as the author of the Bill is a grotesque travesty of the truth. This, indeed, is now generally understood, and it is beginning to be recognised that the proposed legislation, if it requires such commendation, although containing some principles to which we all assent, must have a basis of hopeless immorality. When we reflect upon the crafty ways and the shifty tricks of this legal luminary we may well envy the inhabitants of Utopia. You remember, with a wide tolerance of most men, they drew the line at lawyers. In the Second Book of Sir Thomas More's famous work you will find it stated:—

Furthermore they utterlie exclude and banishe all attorneis, proctours, and sergeauntes at the lawe: whiche craftelye handell matters, and subtelly dispute of the lawes. For they thinke it moste meete, that every man should pleade his own matter, and tel the same tale before the judge that he wold tell to his man of law. So shall there be less circumstance of words, and the trueth shal soner come to light, whiles the judge with a discrete judgement doethe waye the woordes of him whom no lawyer hath instructe with deceit, and whiles he helpeth and beareth out simple wittes against the false and malicious circumventions of craftie children.

Two Great Dangers to the Profession.

Many of us in Scotland have spent time, and energy, and money in struggling against some of the clauses which would be disastrous to the medical profession. In regard to a good many of these provisions, concessions have been promised by the author of the Bill, but it is absolutely necessary that we should watch over its progress. If placed on the Statute Book as an Act it can only be brought into operation with our sympathy and assistance.

To the members of our profession there are two great dangers. It is possible, on the one hand, that the emoluments of a large number of our brethren may be so reduced as to render conditions of life too hard for the successful prosecution of medical practice; and, on the other hand, that a new and subordinate class of practitioners may arise, who have neither the instincts nor the education of the present generation. We earnestly hope that neither of these contingencies may arise. We glory in our medical brotherhood, and have good reason to do so. The discussions on the Bill have taught our profession its power, and have shown its solidarity. If we remain as at present, shoulder to shoulder, the Government must come to terms with us and alter the obnoxious clauses of the Bill.

IMMIGRATION.

There are important matters with which Parliament has been engaged within recent times, with which it is even now occupied, or with which, before long, it must concern itself. Along certain definite lines, in respect of these subjects, we should, in my judgment, use our influence in order to assist social progress. To some of these let me now ask your attention.

As regards the health of the people, let us begin at the beginning, and the obvious commencement is with the addition of inhabitants to this country. For generations we have been the refuge and asylum, not merely of the political exiles, but of the criminal outcasts of other countries. It is high time that this should be put an end to. An Act was passed some years ago regulating the entrance of undesirables into this country; but it is very largely a dead letter, and we still remain the dumping-ground of the rascality of the world. We should learn a lesson from our children in Canada and our brethren in the United States. They do not accept with an equanimity, possibly benevolent, but certainly facile, the entrance of every criminal, lunatic, and degenerative derelict from other countries. They are perfectly right, and the wisdom of their stern regulations is more and more manifest every year.

We have to admit that we are a people of mixed blood; but we need not try to be more mongrel than we really are. We used to be at least a white race, but now there are far too many black and brown and café-au-lait complexions in our streets. It would be a decidedly hopeful indication did we see some more pride of race manifest amongst us to-day. It cannot be said, however, that there is much indication of a growth of common-sense in these directions amongst a nation like ours which seems positively to welcome the introduction of goods manufactured in foreign prisons, to the detriment of our own workmen at home.

EUGENICS.

In this century it is probably inconceivable that any nation can ever attain to such a scheme of marriage as is depicted in the Fifth Book of the Republic; but we can use

mouth and pen in order to further the propagation of our race only along lines dictated by common sense. We must admit that, in such questions, there are enormous difficulties. Heredity and environment are both at work in the formation of character, physical as well as psychical. It is part of the study now termed Eugenics to inquire into and sift out the facts connected with these subjects; and we must remember that in this study we have not merely scientific problems, but we have social duties.

It is probable that each one of us now present is a believer in the doctrines of Weismann. Although the principles he has enunciated are most helpful to us in our conceptions of many phases of evolution, it must be allowed that they in the meantime somewhat increase our difficulties in the way of practical application. The general result, however, is to increase our hopefulness that, by improving the environment, we possess the means of elevating the race. The persistence of the germ plasm, and its independence of all accidental circumstances, furnish cheerful anticipations, could we but have the power of removing the organism from evil surroundings.

One of the most admirable illustrations of this subject is to be found in a very interesting address on the Eugenics Question and its Limitations by Macalister. Macalister prosecuted an inquiry concerning all the marriages in Liverpool between couples both of whom were deaf-mutes and discovered 62 such unions. From these marriages there resulted 219 children, to say nothing of a large number of grandchildren, and there was not a deaf-and-dumb child in the whole of these descendants. He tells us also that in the further investigation into the histories of the children in the Liverpool School for the Deaf and Dumb, where for 15 years records had been kept regarding the parents of those afflicted by these affections, the surprising result was discovered that there had been no deaf-and-dumb child whose parents had been deaf and dumb in the whole of that period. Such facts as these show us how persistence of type in the germ plasm tends to a hopeful view, provided the individual is placed in a satisfactory environment.

We now know how much may be made of Mendelism in breeding certain physical characteristics; but we know nothing of what will lead to the production of higher types. This has been exceedingly well put in an admirable address, "On the Aim and Scope of Eugenics," by Sir James Barr:—

> The difficulty is to know what characters lead to the elevation of the race; but if we do not know all the characters we want, we do know many of those which we do not want, so we should begin our campaign by eliminating the undesirables, the idiots, the imbeciles, the insane, the useless wastrels, the professional pauper, the habitual drunkards, the habitual criminals. There are, of course, certain criminals, such as the burglar, the highwayman, and the forger, who are very clever, and if we are breeding for intelligence it might not be well to exclude them. Many of these men are misdirected geniuses, much more clever and often more honest than your company promoter. Some of these men might make or produce an excellent Chancellor of the Exchequer; scarcely one of them would stoop to a hen-roost, and nothing short of a jeweller's shop or a bank would tempt some of them.

How are we to set to work in order to make use of the forces of heredity and environment? Although the former is largely beyond our control, we may take advantage of our knowledge so far as it goes in order to see that only those who have inherited, and who are likely to transmit, healthy characters are to be the parents of the race of the future. With this end in view, let us segregate the undesirables of every kind in labour colonies, let us treat them with firm kindness, but let us see that they do not give hostages to fortune. It is often held that the practical difficulties are overwhelming, and that it is impossible to carry out such a scheme as this. Plans of this kind have, however, been adopted successfully both in America and on the Continent. There is at least one labour colony in America which costs the community less than half a dollar—about eighteenpence—a year for each inmate, and there is a similar institution in Switzerland, which is entirely self-supporting. Such facts as these point the way for useful legislation in our own country.

We must set our faces against the union of good and pure women with depraved and vicious brutes—this is, indeed, a libel on the lower animals—in order to reform them; or, with decadents and degenerates, in order to develop and elevate them. Some of you will probably remember a series of six plaster casts that used to adorn the retiring room of Professor Laycock in the University of Edinburgh. Two of the casts were taken from a man and a woman who had been inmates of one of the county asylums. The directors or managers of the institution, in their supreme wisdom—or in their benevolent altruism—thought that the two obvious degenerates would either work better, or that they would be more happy, if they became husband and wife. They were married; and the four other plaster casts represent the four offspring—each of which, in a descending series, became more simian, or degenerate.

The celebrated case of "Ada," whose surname has been judiciously hidden from the gaze of the curious, is a terrible instance of the production of the criminal type. Ada was the progenitor of something like 1200 individuals, of whom at least 1000 were criminals, or lunatics, or paupers, or prostitutes, or drunkards. It has been attempted quite recently to prove that the unfortunate Ada was not as black as she has been painted; but the facts are undoubted—that nearly 85 per cent. of her numerous descendants were hopeless degenerates.

Much may be said for the old monastic and conventual system. The frail Ada might have done well either in the choir or in the kitchen of a sisterhood of perpetual adoration; while the elusive Crippen would have been far better occupied as a gardener or even a cellarman in some working order than in exercising his misdirected energies without guidance and restraint. It is to be remembered that even the best of us may be faulty in practice—albeit sterling in principle. You remember how Samuel Johnson, in speaking of his great friend, Dr. John Campbell, makes the remark:—

> Campbell is a good man, a pious man. I am afraid he has not been in the inside of a church for many years; but he never passes a church without pulling off his hat. This shows that he has good principles.

In another part of the same charming work the ponderous Doctor once more speaks of his good friend as—

> A man of good religious principles, though I am afraid he has been deficient in practice. Campbell is radically right, and we may hope that in good time there will be good practice.

And yet again, this time after the death of his friend:—

> I loved Campbell; he was a solid, orthodox man; he had a reverence for religion. Though defective in practice, he was religious in principle

If the practical outcome in the case of even the best of men falls so far short of a correct standard, what can we say of the worst of them?

Some of our friends are not in favour of the idea that the weak should be taken care of and that the wicked should be kept from working mischief. They believe that Nature should be allowed a free hand—that we ought to trust to the survival of the fittest. They are of opinion that debauchery and disease should be allowed to carry out their work of extermination without hindrance. They tell us that we are hopelessly wrong in rescuing the unfortunate inebriate from the gutter, instead of allowing him to snore away his life in a hard frost or in a sleety storm. Our good friends of this way of thinking (and many of them, it may be said, are most genial and kindly souls) altogether forget that the survival of the fittest is not necessarily the survival of the best.

If we are to enter upon any socialistic legislation we must do it thoroughly—half measures are of no use. The better classes of our fellow working men are now much concerned about social problems of this kind, and we who exert wide influence upon large numbers of them should consider well how we are to use it for further social reform. The supreme importance of a healthy stock; the marriage in the prime of life of the highest types of our fellow men and women; the due performance of every paternal and maternal duty—such are, it seems to me, the most pressing social responsibilities which we have to impress at the present moment upon our lay brethren.

PHYSICAL DEVELOPMENT.

In respect of the education of the people, we have, as medical men, for a long time wisely taught the absolute necessity of caring for physical development and bodily health. The early correction of inherited or acquired defects is an aim worthy of our best endeavours. The system of school inspection by medical officers now affords a basis for concerted action. The healthy training of the body is the only foundation on which the healthy development of the mind may be built. All methods of training the muscular system are of practical utility.

One of the best courses open to us is to emphasise the usefulness of military training, which at once tends to the health of the body and to fitness for defence of the

country. Many of us now present here must have regretted that, when the old age pensions were instituted, the legislature did not make it necessary that those who are, in 20 years or so, to receive those pensions, should have performed the elementary duty of being thoroughly drilled. When we look at the Territorial Force of to-day we find it is composed of the same types of men with public spirit as those who constituted the Force which it has superseded. Would that it were extended! One of the most hopeful features of the present day is the institution of the youthful scouts of both sexes. They, and the school cadets, somewhat raise our anticipations for the future.

Again, general emulation in games is vastly better than standing around gazing at a professional combat by hired gladiators, where the spectators render the mental atmosphere as lurid as they make the ground filthy. Each of the spectators would certainly be much better employed in some healthy game, or, in a walk in the country, than in betting and swearing and spitting while watching a contest of professional performers.

INSTILLATION OF SOUND IDEAS IN CHILDREN.

We should like to see the existence of high ideals, even in infant schools. The example of our brethren in the United States is entirely admirable. From their earliest years the children are taught to have pride in their country and love for their flag. Many of us who have spent long periods away from our native land know well what a warm rush of feeling arises when we catch sight of "the old rag." All of us delight in seeing it waving on the breeze. One of the weakest acts of our present Prime Minister was to discourage the hoisting of our flag upon our public buildings on Victoria Day.

Our children in Canada, and probably in every other Commonwealth, Dominion, or Union of the Empire, can teach us lessons in this respect. Just the other day, on the declaration of the results of the elections in Vancouver, an excited alien seized one of the British ensigns adorning a building, tore it down, and danced upon it in the mud. He was immediately the centre of an interested crowd. Forced upon his knees, he was compelled to offer the most abject apology to the flag, and thereafter, before being allowed to seek retreat, he was obliged to sing "God Save the King" three times from beginning to end, prompted by word and deed; he then received a somewhat forcible dismissal. It is doubtful whether such an incident in this country would arouse more than a shrug of the shoulders.

In the cities a love of rural life may well be inculcated. Some of you may have read the interesting work of Canon Horsley upon his labours amongst the poor in London. He has done a great deal of loving work for the children by sending them out to enjoy holidays in the country. He tells a pathetic story of one youngster whom he met on his return from a day in a beautiful country place. On asking the boy how he enjoyed it, he was astonished to get the reply that it was "beastly"; and when pressed for a reason for this opinion the boy said there were "no rows, no fights, no funerals—no nothing."

It often seems to me that the schools of to-day do not foster the acquirement of gentle manners as well as was the case with our old parish schools. On speaking, not merely to schoolmasters, but to inspectors of schools, upon this matter, they have told me that it is the fault of the present system; that the schoolmaster is not expected—nay, he is even forbidden in many instances—to take any interest in, or to influence the conduct of, the children out of school hours. If this be the case, what can we expect of many of the children living in the dens of our great towns? Once, not very long ago, a benevolent old lady met a small boy, who was a member of a children's fresh-air holiday expedition. She stopped and said kindly to the little mite: "I suppose you are one of the fresh-air children?" His reply was startling to the poor old lady. What he said was: "Not so very damned fresh neither"!

Is it too much to expect that before the children leave school they should not only be brought within the influence of refining agencies, but that they should also be subjected to patriotic impressions? It seems to me that they never can be too young for the instillation of sound views. We must use all our influence in order to impress on each and all within our sphere of influence that there are no rights unaccompanied by duties: no privileges unattended by responsibilities.

PRACTICAL BEARINGS.

What are the practical bearings of these points on the treatment of the medical aspects of social questions? The reply is easy. We have to answer to our fellow-citizens and to the Commonwealth for our conscientious discharge of every trust reposed in us. One of our duties is to speak what we believe to be the truth, frankly and fearlessly.

Much of our work is in direct opposition to the obvious tendencies of nature. We labour day and night to compel the unfit to survive. Undoubtedly the ordinary dictates of humanity demand this course. The common-sense of humanity, nevertheless, does not suggest that the unfit should be the parents of the future race.

Just four weeks ago Lord Rosebery took occasion to ask, in his brilliant rectorial address, whether we are not in danger of becoming a "spoon-fed nation." He is not alone in his fears. The belief is entertained, not only by the lovers of our land, but by those who cannot be looked upon as particularly friendly. In his later years, that man of blood and iron, the late Prince Bismarck, remarked contemptuously, "England! Pooh! England has run to flesh." Is there no truth in his powerful gibe? We are striving to make the bed of everyone too soft. We attempt to construe crime as a symptom of disease. We labour to rescue the unfit from extinction. We encourage our degenerates to flourish. We stimulate the breeding of hooligans. We even unite our lunatics in the bands of holy wedlock.

If the sturdy old individualism by which our nation was fashioned is to be superseded by a brand-new Socialism, let us see to it that the new order is, as far as may be possible, based upon scientific principles. By all means let us persevere along the fruitful lines of public health reform followed during the last two centuries—improving the dwellings and bettering the conditions of the working men. Above all, let us care for the children not merely by providing them with education, but also with food when necessary.

To one point you will perhaps let me, in this place, briefly refer. It is assuredly a foolish arrangement to allow the tainted offspring of the criminal classes to sit side by side with the innocent children of the respectable artisan. This is another cogent reason for segregating the criminal and the degenerate, and for State rearing of their offspring when they unhappily have any.

By using all our influence in such directions we can greatly aid social reform, and certainly it will be better for this country if we can carry out such improvements. Progress can never be attained by allowing the alien to crowd out our better-class workmen; by favouring the free entry of foreign goods—especially those manufactured by the criminals of other countries, whom we therefore assist to maintain—or by enacting crushing taxes upon the land, so that it is impossible to sustain a healthy population upon it. No, the British workman is already showing signs that he is tired of such futile expedients; and if we can help him with the result of our wide experience we shall be doing our best for the future of our nation. We have, no doubt, many different ways of regarding such problems, and most varied methods of solving the questions before us; but our aims are one—the elevation of the race.

ROYAL SOCIETY OF ARTS.—The current session of the Royal Society of Arts was opened on Nov. 15th with an address by Lord Sanderson, a vice-president of the Society and chairman of the council. Taking for his principal subject the modern development of international intercourse, he dated its origin from the fifteenth century when the maintenance of permanent diplomatic agents at foreign courts became general in Europe, simultaneously with the establishment of permanent armies. Many illustrations of the recent increase of international intercourse were drawn from the work of the post-office, the telegraph service, oversea passenger traffic, statistics of imports and exports, and international exhibitions and congresses. After concluding his address Lord Sanderson presented a number of medals to various recipients. Three of these were Fothergill medals for mine rescue apparatus—a gold one each to Mr. H. A. Fleuss and Mr. W. E. Garforth, and a silver one for apparatus submitted by the Mining Engineering Company. Dr. Leonard E. Hill received a Royal Society of Arts medal for a paper read by him on Caisson Sickness and Compressed Air. Mr. James Cantlie received a similar medal for a paper on Plague and its Spread.

THE TREATMENT OF CLEFT PALATE.

BY R. W. MURRAY, F.R.C.S. ENG.,
SURGEON, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL; LATE SURGEON, LIVERPOOL INFIRMARY FOR CHILDREN.

AN endeavour to trace any surgical procedure to its origin is interesting, and often very instructive. Anyone engaged in such a pursuit soon discovers that the true course of surgery is by no means smooth and straight; in fact, to retrace any surgical footpath is not always an easy matter, the way is so tortuous, the milestones so many, and the light so often fails. However, many surgical procedures can be traced to their origin, and probably none with greater certainty than that relating to the operative treatment of cleft palate.

There can be no doubt that M. J. P. Roux, Professor in the Faculty of Medicine of Paris, was the first surgeon to close a cleft of the palate. The way in which the operation was suggested to him, and the brilliancy of the result, is one of the romances in surgery. One morning early in September, 1819, Mr. Stevenson, a young Canadian, studying medicine in Paris, who had a cleft of his soft palate, called upon the professor, who was then one of the luminaries in Paris, and asked him if he could stitch his palate and so improve his speech. Roux said he would try; he pared the edges of the cleft and brought them together with sutures. Union followed; the palate became like a normal one, and when the youth appeared amongst his former friends the change in his voice was such that he could scarcely be recognised as the same person.

It seems strange that so remarkable an achievement should not have made more stir in the surgical world. No doubt other surgeons tried, but the operation was tedious, painful, and exhausting, and as failure was more frequent than success few persons had the courage to submit to such an ordeal. Liston, writing in 1831, said only fissures of the soft palate could be operated upon. "In some cases the extent of the separation is great; in others the edges are readily approximated by making the patient throw the muscles into action. The latter class admit of operation with a view to permanent union of the edges of the fissure." He considered the operation very liable to failure.

During the next ten years no real interest appears to have been taken in the matter, but in 1840 the whole surgical world was stirred by the brilliant results obtained in subcutaneous surgery by Dieffenbach and Stromeyer, the former by subcutaneous myotomy for strabismus and the latter by subcutaneous tenotomy for club-foot. This was the birth of plastic surgery. Tenotomy and myotomy at once attained popularity and were generally recognised as sound surgical procedures.

In this movement attention was again directed to the treatment of cleft palate, and to Dieffenbach and Sédillot we are indebted for a distinct advance in this branch of surgery based upon the principle of myotomy and tenotomy, for they were the first surgeons to make lateral incisions parallel to the cleft in order to lessen the tension on the stitches. Though surgical interference was at this time strictly limited to fissures involving the soft palate only, still lateral incisions rendered success more frequent in the slighter cases, and enabled some of the wider gaps to be closed successfully. It was, however, Sir William Fergusson who first explained the real object of these lateral incisions, which had been made without any definite anatomical reason. In 1844 Fergusson read a paper before the Royal Medical and Chirurgical Society in which he explained how the muscles of the palate act when it is cleft. From an actual dissection he was able to demonstrate that the levator palati, the palato-pharyngeus, and palato-glossus widen the cleft when they contract, and consequently the action of these muscles was responsible for many failures after the operation of Roux, who never made lateral incisions. Fergusson advised tenotomy of these muscles, which he did by passing a specially constructed knife through the cleft and divided the muscles on the posterior aspect of the palate. He thus placed the incisions for the relief of tension on a sound scientific basis. Up to that time no English surgeon had succeeded in closing, or even had attempted to close, a cleft of the hard palate.

The next conspicuous advance originated in the mind of an American surgeon. In 1843 Dr. T. Mason Warren of Boston published an account of several cases in which he had succeeded in closing congenital clefts which involved both hard and soft palates. Sir William Fergusson, referring to this in the first edition of his "Practical Surgery," published in 1852, says, "Until a very recent date no attempt has been made by surgeons to close a gap in the hard palate, excepting by means of an obturator, which has always been supplied by a dentist. Dr. T. Mason Warren of Boston has, however, closed the fissure here, as well as in the soft palate, by a proceeding strictly surgical; he dissects the soft tissue from the hard vault of the mouth, between the margins of the cleft and the alveoli, and then closes them in the mesial line by a proceeding analogous to the operation in the soft parts, and reports (in the *New England Quarterly Journal of Medicine and Surgery* for April, 1843) most favourably of the result. I have resorted to the operation in several instances, but without success; yet the plan seems so clever and reasonable that I cannot but recommend it for further trial."

When, in 1847, chloroform was introduced to surgical practice one would have thought that its administration would have greatly facilitated operations upon the palate, and would soon have rendered the operation feasible in childhood; but it was not so. The reasons probably were the want of an efficient mouth-gag, without which the surgeon could not perform the operation with the patient under an anæsthetic, and the high mortality attending the administration of chloroform in operations about the mouth and throat.

Writing so late as 1864 Sir William Fergusson says: "I have never operated under chloroform, and whilst I do not deny the possibility of doing so, I am of opinion that as a rule it is absolutely necessary to have the patient conscious so that he may facilitate the steps of the operation in various ways."

It should be noticed that Dr. Mason Warren, in order to close a cleft of the hard palate, separated the soft tissues from the hard vault, beginning at the margin of the cleft and working gradually outwards towards the alveolar margin. The difficulty of the operation and the uncertainty of the results soon induced surgeons to modify the procedure. Mr. Pollock of St. George's Hospital, who paid great attention to this branch of surgery, recommended that after separating the soft parts from the bone lateral incisions should be made as far from the margins of the cleft as possible in order to avoid the chance of sloughing. "The edges being pared, sutures should be passed into the slips of soft tissue which now lie between the opening and the lateral incisions. An improvement to the support given by these sutures is obtained by passing a broad suture through the lateral incisions and then including with its embrace both flaps. This not only serves to support the flaps, but it prevents the healing of the lateral incisions until union has had time to take place between the margins of the opening."[1]

A further and very important modification was made by Langenbeck. Instead of beginning the separation of the soft parts from the bone at the margin of the fissure, he made lateral incisions parallel with the alveoli through the soft parts down to the bone and raised the muco-periosteum towards the margin of the fissure, his object in raising the periosteum being that new bone might be developed which would fill the gap. It is Langenbeck's modification of Warren's operation which is commonly practised to-day.

Sir William Fergusson suggested another modification of the operation, in which an incision was made on each side of the fissure and the bone divided longitudinally with a chisel, the two edges being forced into contact. Although in his own hands some satisfactory results were obtained, further experience has led to the abandonment of the operation, which is unnecessarily severe and liable to be followed by necrosis of the divided bone.

Jan. 14th, 1868, is a very important date in the history of the surgical treatment of cleft palate, for on the evening of that day Mr. (afterwards Sir) Thomas Smith, who was then assistant surgeon to St. Bartholomew's Hospital and surgeon to Great Ormond-street Hospital for Children, read a paper before the Royal Medical and Chirurgical Society on the Cure of Cleft Palate by Operation in Children. In the course of the paper he said: "The advantages of being able to cure cleft palate in childhood will

[1] Transactions of the Royal Medical and Chirurgical Society, 1856.

at once be conceded by those who are familiar with the deformity and the inconvenience it entails. A resolute and intelligent adult patient, after a successful operation, may acquire by his own efforts, or with the aid of an instructor, the power of distinct and normal articulation. But in some the difficulty of unlearning an almost life-long habit is wellnigh impossible. It is probable that were the deformity of cleft palate cured in childhood, before the power of speech is being acquired, there would be less difficulty in teaching a child to articulate distinctly. At least it is certain that the earlier the cure was effected the less difficulty would the patient have in learning to speak plainly."

Up to that time the general practice of surgeons had been to postpone the operation until about puberty. Mr. George Pollock, writing in Holmes's "System of Surgery" in 1864—only four years before Mr. Smith read his paper—gives a clear and forcible expression of opinion as to the age at which a cleft of the palate should be operated upon. He says: "The age of the patient is a matter of some consideration to the surgeon who proposes to operate for the permanent closure of a cleft palate. There can be no doubt, as a general rule, that the patient should be old enough to desire the operation, should have sufficient determination to endure it, and should be able to estimate the advantages to be derived from it. For many reasons the age of 15 appears to be the earliest period for the operation; often a later period is desirable, though in some few instances it has been performed on younger children." Mr. Pollock goes on to observe that "the operation requires every assistance the patient can afford by quiet endurance of pain and keeping the mouth open even to a tedious and painful extent; that bleeding is often abundant and apt to produce fainting; that chloroform is of no assistance but inconvenient in its administration, and can never be sufficiently given to produce insensibility for the entire period required to complete the operation. When it is known that towards puberty the operation is often resolutely submitted to, the profession may feel satisfied that the use of the artificial plate to the period of puberty, with the option of the operation then, is the treatment which should be adopted by the surgeon, is a principle which if followed will give the most satisfactory results, and is a rule in surgery which, in the opinion of the author, should have no exception." This may be taken as representing the attitude of most of the surgeons in London regarding the operative treatment of cleft palate at the time Mr. Thomas Smith related his experience.

In order to render the operation possible during childhood two things were essential, an efficient mouth gag and a general anæsthetic. Mr. Smith exhibited at this meeting a mouth gag he had devised which is still known by his name. "Chloroform," he said, "can and should be used, and thus the operation may be performed with far greater rapidity and precision than when the surgeon is dependent upon the self-control of even the most courageous patient." Eleven cases were described in which chloroform had been administered and the mouth gag employed. Eight of the 11 cases were children under 11 years of age, the youngest being 2 years old. In all these 11 patients the soft palate only was dealt with, no attempt being made in any case to separate muco-periosteum from the roof of the mouth, nor to unite the fissure of the hard palate. In two cases the cleft was confined to the soft palate; the result in both was entirely satisfactory. In the remaining nine cases there was a fissure of the hard palate to a greater or less degree; of these, six were successful and three unsuccessful. The reason for closing the soft palate first was that the cleft in the hard might diminish in size.

Mr. Smith's communication forms a most conspicuous landmark in the surgical treatment of cleft palate; the operation was at once raised to a higher level, and a vision of many and better things quite clearly seen.

Though at the present time all surgeons recommend that a cleft of the palate should be closed completely during early life, there is by no means a general consensus of opinion as to how early in life the operation should be performed. Is it better for the patient that the operation be undertaken during early infancy or during early childhood?

In endeavouring to answer the above question one must above all things remember that the main reason for the operation being undertaken is that the powers of speech may be rendered more perfect than they otherwise could be. I wish to emphasise this point, because in England at the present moment there are two distinct schools of thought, or rather of practice, so far as cleft palate surgery is concerned.

Mr. Arbuthnot Lane maintains that the cleft should be closed during early infancy, in fact, as soon after birth as possible; and that in the ordinary type of the deformity, where there is a complete cleft of the lip and palate, the palate should be operated upon first. Now it must be obvious to anyone who is familiar with the state of affairs that a complete cleft of the palate cannot be closed during infancy by the usual method of operating. Mr. Lane has, however, overcome this difficulty in a most ingenious manner. He raises from one side of the palate a large flap so fashioned that it hinges on the whole of one margin of the fissure, and turning it over he tucks it under a small flap raised from the margin of the cleft on the other side. The flap which is turned over includes both hard and soft palate; its raw surface looks towards the mouth, and must, of course, heal by granulating.

Quite apart from the fact that this is the only way (except Brophy's method, about which I will speak presently) in which a cleft of both hard and soft palates can be closed during early infancy, I have heard it stated as a strong argument in favour of Lane's turn-over flap that the gap can thus be closed more easily and much more certainly than if the operation be postponed until early childhood and Langenbeck's method adopted. Even if that point be granted, surely one aims at something more than the mere closure of the fissure. The chief reason for performing the operation is not that the gap in the palate may be bridged over, but that articulation may be rendered as perfect as possible. The operation is undertaken for the ultimate benefit of the patient, and not for the immediate satisfaction of the surgeon. The end result is the true test of success.

After 20 years' experience in cleft-palate work, and with some considerable knowledge of the after-history of my cases, I am convinced that for a person to speak clearly and distinctly a well-formed and freely moveable soft palate is absolutely necessary. Now in Lane's turn-over flap the raw surface left uncovered will heal by granulating and consequently must contract; excess of scar tissue in the hard palate does not matter in the least, but makes all the difference in the world if present in the soft palate, which instead of being well formed and freely moveable will be ill formed, short, and so tightly drawn that the patient cannot move it at all; due, of course, to being composed so largely of cicatricial tissue. Consequently articulation must be sadly defective.

If, on the other hand, the operation be postponed until the child is two or three years of age, by paring the edges of the cleft and bringing them together in the middle line, not only may a well-formed soft palate be fashioned, but it will also be freely moveable, for the muscles retain their normal actions, and there is only a thin central line of scar tissue.

I wish it to be clearly understood that I do not object to the operation during infancy provided a soft palate resembling the normal one in shape and function can be made. The earlier in life such a state of affairs can be brought about the better, but speaking from my own experience I can say that when the cleft in the palate is complete and associated with a hare-lip I have obtained the best results in appearance and in speech by operating upon the lip at the age of 3 months and closing the palate by Langenbeck's method when the child is 3 years old. After all said and done, the true result, so far as speech is concerned, is entirely a question of evidence, and some years ago I suggested that a demonstration of cases should be held so that surgeons who advocate the turn-over flap (Lane's method) might produce their cases and surgeons who prefer to operate during early childhood by the ordinary method (Langenbeck's) might produce theirs. So should we learn wisdom, not from the writings of the surgeons, but from the lips of the children.

A demonstration such as I have mentioned took place at a meeting of the Surgical Section of the Royal Society of Medicine on May 9th of this year.[2] Though a great number of cases operated upon by the ordinary method were shown, for some reason or other only a few cases illustrating the results of Lane's method were brought forward. However,

[2] THE LANCET, May 20th, 1911, p. 1351.

after hearing the children speak there could be no doubt as to the respective merits of the two methods. In several instances in which a complete cleft of the hard and soft palates had been closed by the ordinary plan (Langenbeck's) during childhood the speech was natural, and the words "British constitution" repeated clearly and distinctly. On the other hand, in any case in which the cleft had been closed by Lane's method, articulation was so very imperfect that it was difficult to understand what was said. In all cases in which articulation was distinct the soft palate was seen to be normal in form and in movement; in all cases in which Lane's method had been used the soft palate was short, stiff, and stationary, accounting for the sad defect in articulation, for which unfortunately no remedy can be supplied. The evidence thus obtained from patients who had been operated upon was overwhelmingly in favour of closing the cleft in the ordinary way, whilst the extremely unsatisfactory articulation of patients operated upon by the turn-over flap method proved that it is wrong in principle, defective in practice, and to be utterly condemned.

Though I have nothing very novel to record in the way of operative detail, still from practical experience I have learnt one or two points which may perhaps be of some service to others.

Brophy's Operation.

After reading Dr. T. W. Brophy's account of his operation in the Transactions of the American Surgical Association, 1904, I determined to give it a trial. It was not long before I had a suitable case; the infant was 3 weeks old, and had a complete cleft of the lip and palate. Though I had studied carefully Dr. Brophy's instructions, my operative efforts were not crowned with success. After making the necessary incisions I tried very hard to force the superior maxillæ together, but instead of the bones sliding towards each other in the same plane, and so obliterating the fissure in the palate, in spite of all I could do they would hinge at the sides of the fissure in such a fashion that any further pressure would only have resulted in the alveolar margins of either side meeting in the middle line. The operation was, of course, abandoned. In another case I did succeed to some extent in approximating the bones in the manner Brophy describes, and after passing the silver wire sutures found I had lessened the cleft in the palate by about a quarter of an inch. The shock attending the operation was considerable, the infant never regained what it had lost, and died a few months later. I also had an opportunity of doing the operation in the post-mortem room upon an infant with a complete cleft of the palate and lip who died from gastro-intestinal trouble before being operated upon. Again, in spite of very free lateral incisions, the bones would not glide; they would hinge, and any lateral pressure I could exercise only resulted in the alveolar margins meeting in the middle line. I have never attempted the operation since. Though it is more than probable that in my case it was the operator and not the operation that was at fault, still so far as I know Mr. Edmund Owen is the only English surgeon who speaks well of the procedure.

Langenbeck's Operation.

This is the operation I perform, and it is so familiar from being described in all text-books on general surgery that I will only mention some points which I have found of practical value. Of course, no operation upon the palate must be undertaken at any age unless the general health of the patient is good and the condition of the mouth, throat, nose, and ears is beyond suspicion.

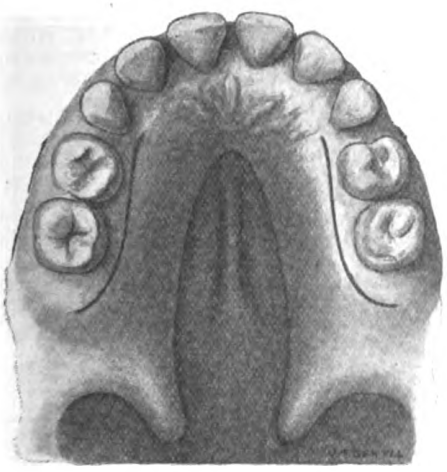
Age at which the operation should be performed.—This will depend to some extent upon the width and length of the fissure. When it is narrow and involves the soft palate only I have frequently operated with success during infancy, but as a rule prefer to wait until the second or third year. My reason for not operating during the first few months of life, even when the cleft is confined to the soft palate, is that, apart from the tissues being very friable, the bifid uvula is then so small that after paring the edges there is not much uvula left. It is very important to make a good-looking soft palate and uvula, resembling as nearly as possible the normal, and when I think I have sufficient material to do this I arrange for the operation to take place. As I have pointed out already, the future power of articulation chiefly depends upon the shape and movements of the soft palate. In the usual type of the deformity where there is a complete cleft of the lip and palate my general practice has been to operate upon the lip when the child is 3 months old, and upon the palate at the age of 3 years.

Time of year.—I prefer to operate during the summer months, and consider the cleft palate season opens on May 1st and closes on Oct. 1st.

Preparatory treatment.—As it is important to syringe the mouth and nostrils after the operation in order to keep them clean, this performance should be thoroughly rehearsed several days beforehand. Every child will not submit to it either before or after operation, but many will, and I have found it most useful—in fact, it is the only way in which the mouth and nasal cavities can be kept clean.

Anæsthesia.—Chloroform should be given, and the manner of its administration is a matter of great importance. Continuous anæsthesia, which can be produced by using Junker's apparatus, is very convenient to the operator but very dangerous to the patient. I speak not from my own experience, for I have never used this method, but from what I have seen in the practice of others. Chloroform should be given on lint in the ordinary way. The administration of the anæsthetic is necessarily intermittent, and so the period of the operation lengthened, but this is more than compensated for by the knowledge that your patient is with you all the time and not drifting to an unknown land.

Position of the patient.—I prefer to have the child lying on the back, with the head and shoulders raised. I stand at the right hand of the patient.



Incisions, &c.—The whole cleft is closed at one sitting. I begin by making the lateral incisions and raising a muco-periosteal flap (Figs. 1, 2, and 3). I then pare the edges of the fissure, taking pains to cut obliquely and so secure broad raw surfaces (Fig. 4). Up to this point I use gauze dabs to clear the blood and mucus from the mouth and throat, but after paring the edges I suck the blood and mucus away with a glass syringe which has a piece of rubber attached. The raw surfaces of the cleft, upon which so much depends, are thus less irritated than by sponging; besides which, the more sponging the more mucus secreted.
